# Polar ozone loss process

# Kinetics of the dimer cycle

Balance of  $\text{ClO} / \text{ClO}_x$  and ozone loss rate are governed by:

**Step (1): „Forward Reaction“**

**Step (2): „Thermal decomposition“**

$$k_{\text{eq}} = k_f / k_b$$

**Step (3): „Photolysis“**

$$\text{Rate} = J_{\text{ClOOCi}} \times [\text{ClOOCi}]$$

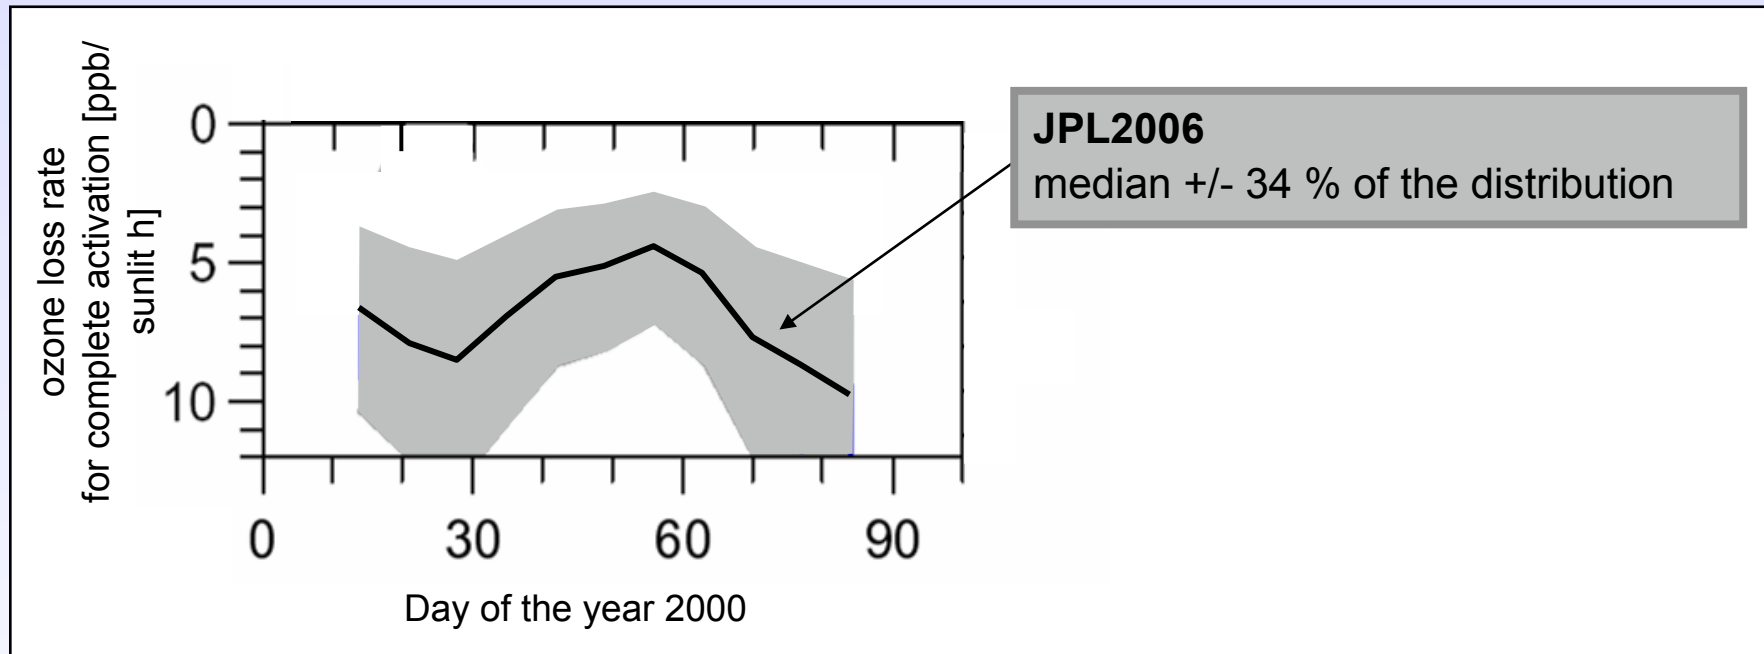

**Step (4):  $\text{Cl} + \text{O}_3 \rightarrow \text{ClO} + \text{O}_2$ :**

Rapid.  $\text{ClO}/\text{ClO}_x$  and ozone loss rate not sensitive on rate of step (4).

# Model uncertainties

## Monte Carlo simulations of model uncertainties

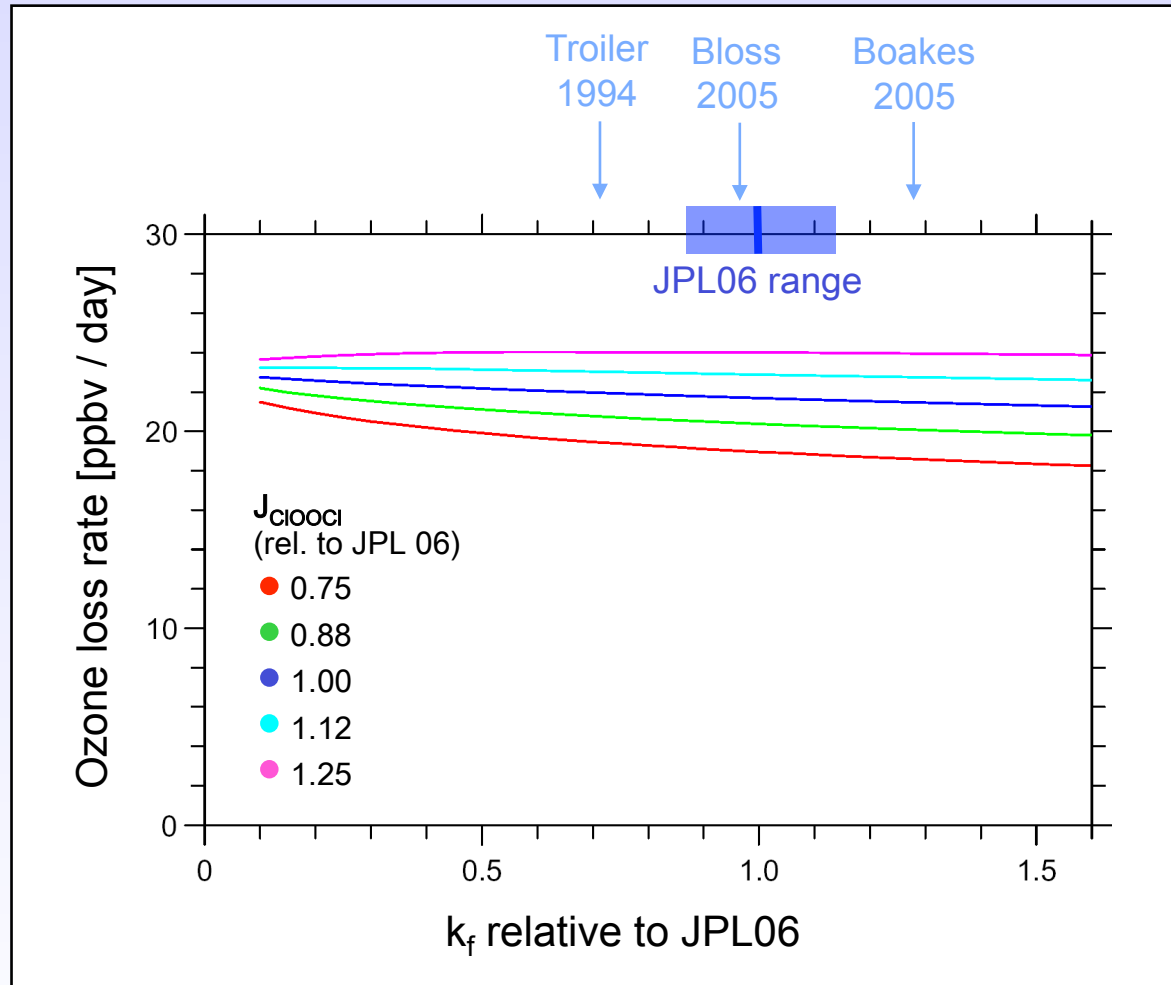

hundreds of model runs distributed according to the uncertainties stated in JPL2006

=> up to a factor of 3 uncertainty due to uncertainty in gas phase kinetic data

## 24 hour average ozone loss rate versus $k_f$

195 K, 50 hPa, early February,  $\text{ClO}_x = 2$  ppbv, little sensitivity on  $k_{\text{eq}}$

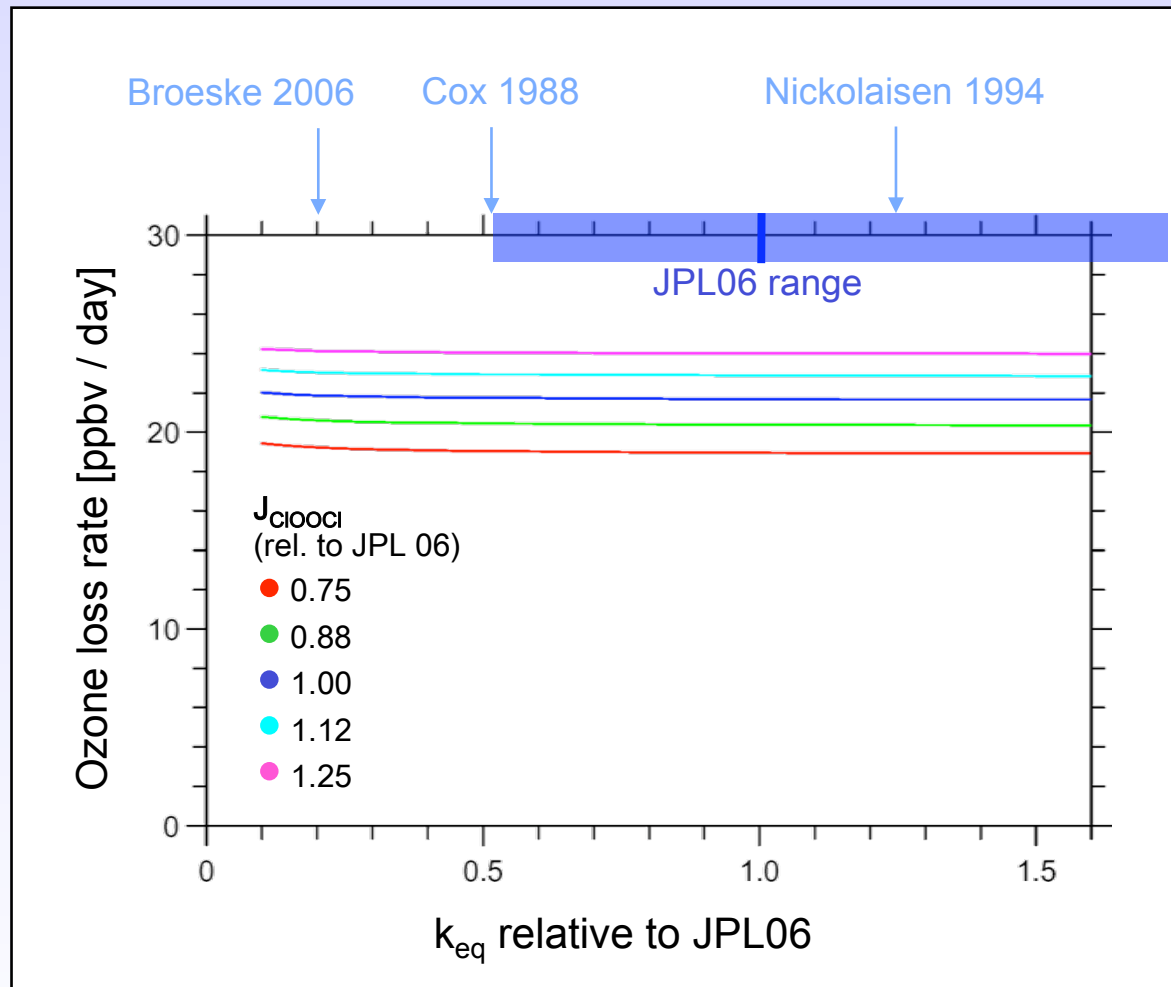

=>

Calculated ozone loss rate is fairly insensitive on uncertainties in  $k_f$

## 24 hour average ozone loss rate versus $k_{eq}$

195 K, 50 hPa, early February,  $ClO_x = 2$  ppbv, little sensitivity on  $k_f$

=>

Calculated ozone loss rate is fairly insensitive on uncertainties in  $k_{eq}$

## 24 hour average ozone loss rate versus J

195 K, 50 hPa, early February,  $\text{ClO}_x = 2$  ppbv, little sensitivity on  $k_{\text{eq}}$

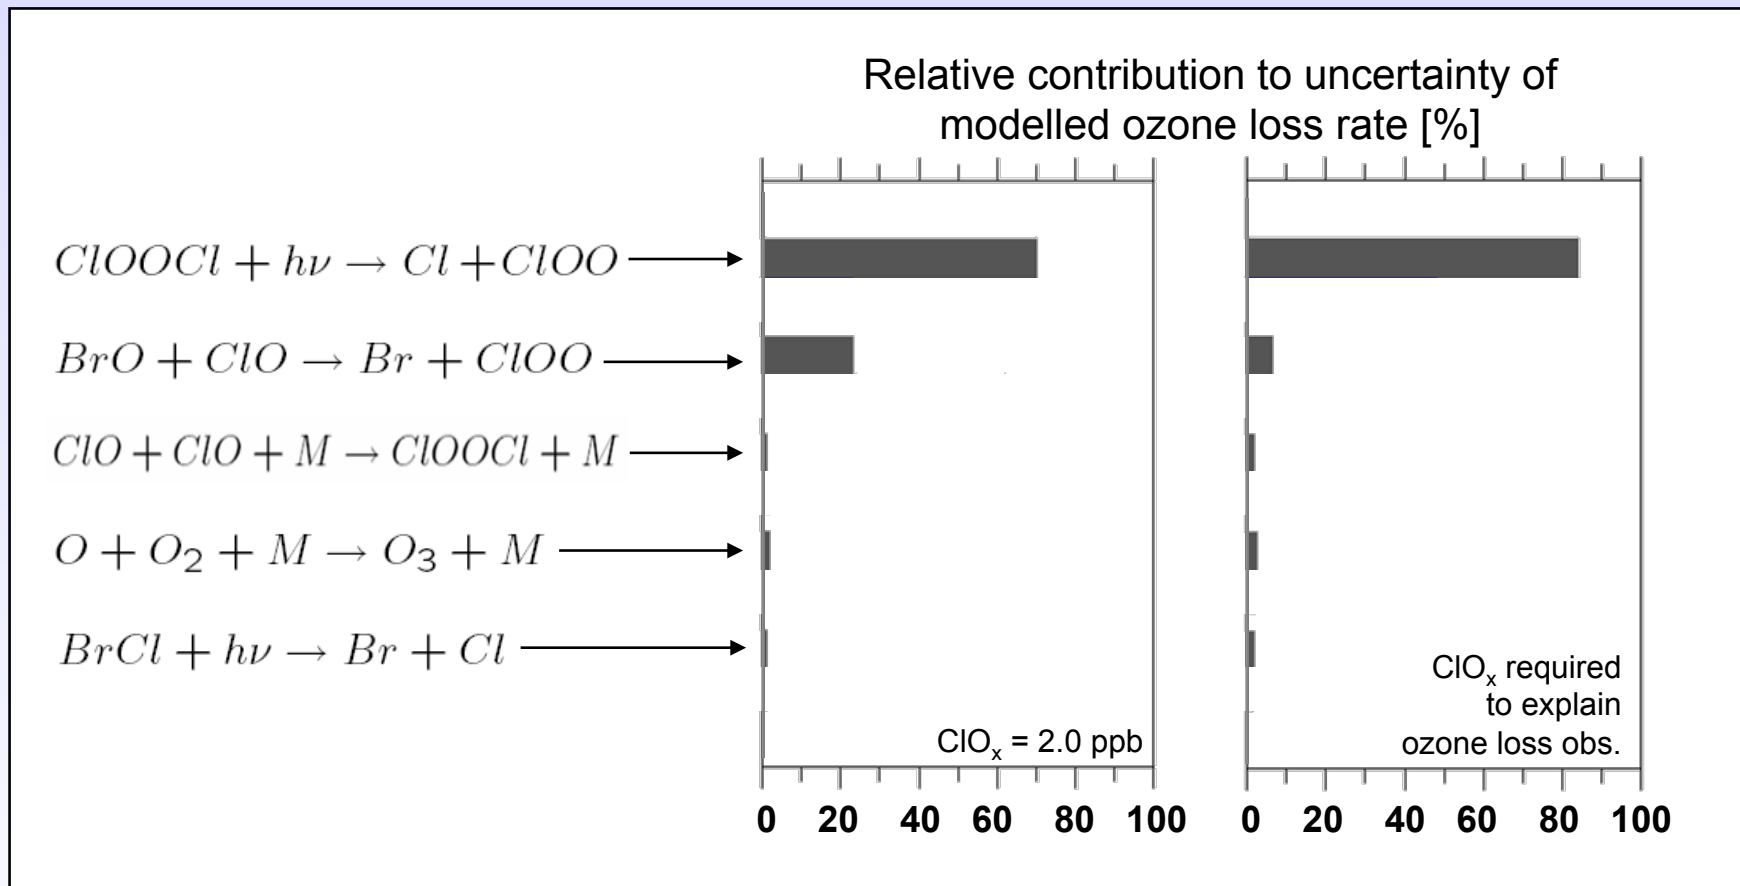

=>

Calculated ozone loss rate is highly sensitive on uncertainties in J

# Sources of model uncertainties

from Monte Carlo simulations

Frieler et al., PhD work, 2006

## Sources of uncertainty in J

$$J = \int \sigma(\lambda) \cdot \Phi(\lambda) \cdot I(\lambda) d\lambda$$

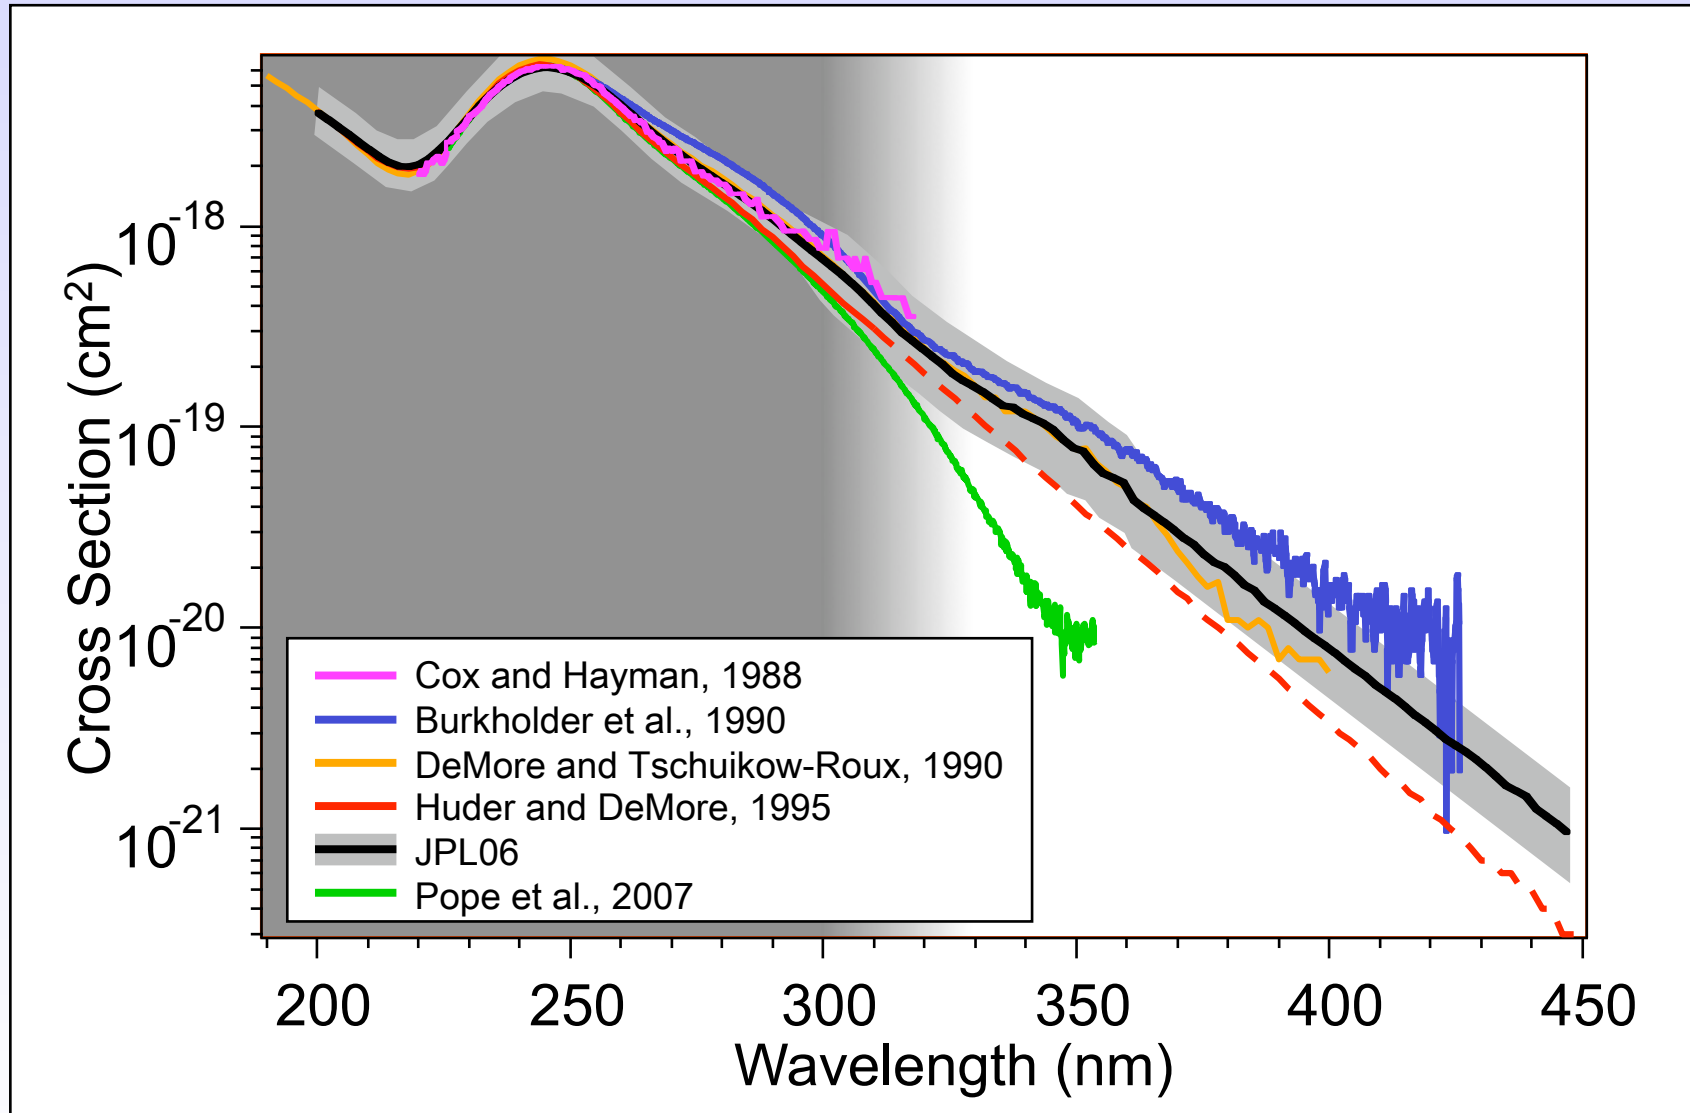

absorption cross sections:  
from lab measurements

Quantum yield: 0.9 - 1.0

Actinic flux (i.e. photon flux):  
calculated with radiation transfer model

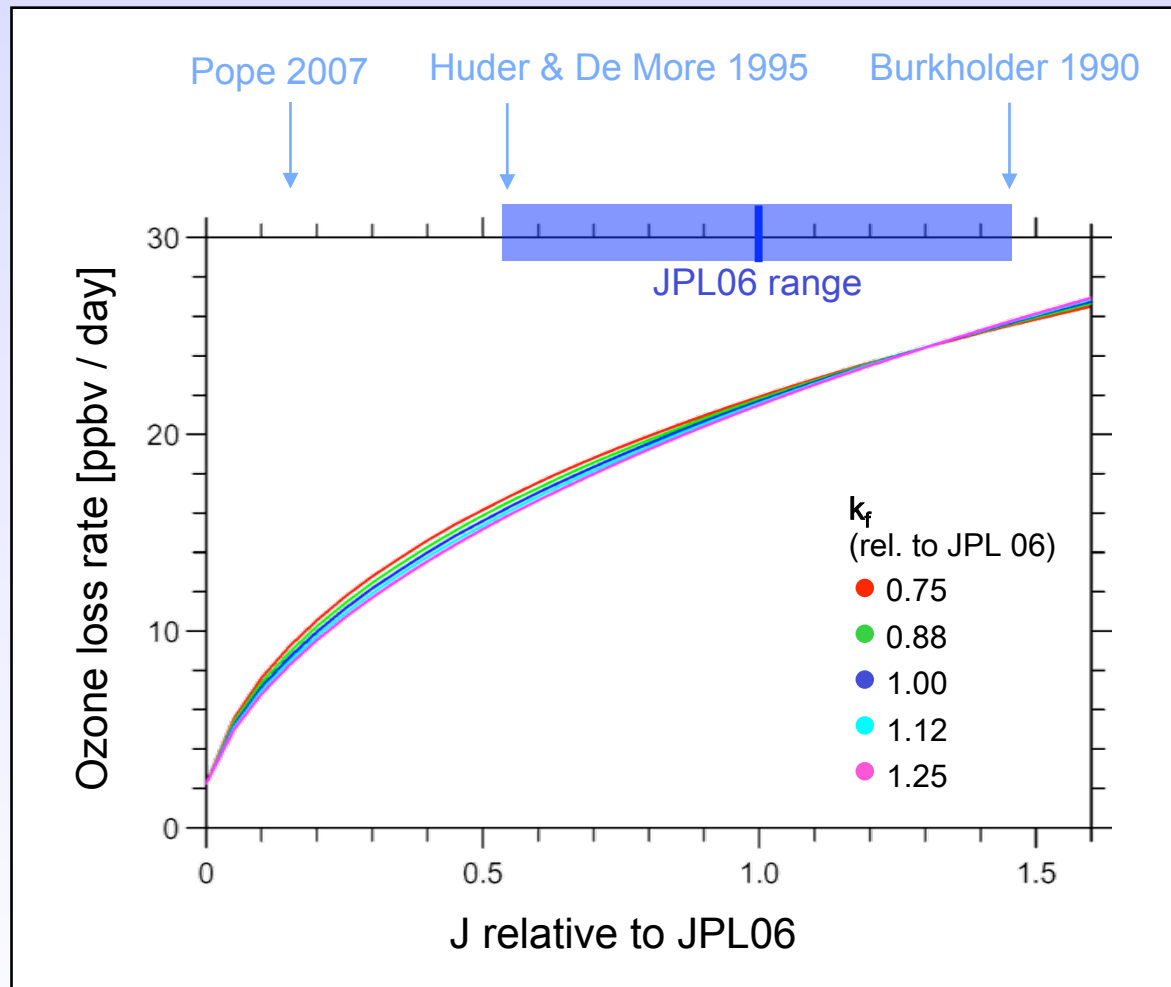

## Measurements of ClOOCl cross sections

## 24 hour average ozone loss rate versus J

195 K, 50 hPa, early February,  $\text{ClO}_x = 2$  ppbv, little sensitivity on  $k_{\text{eq}}$

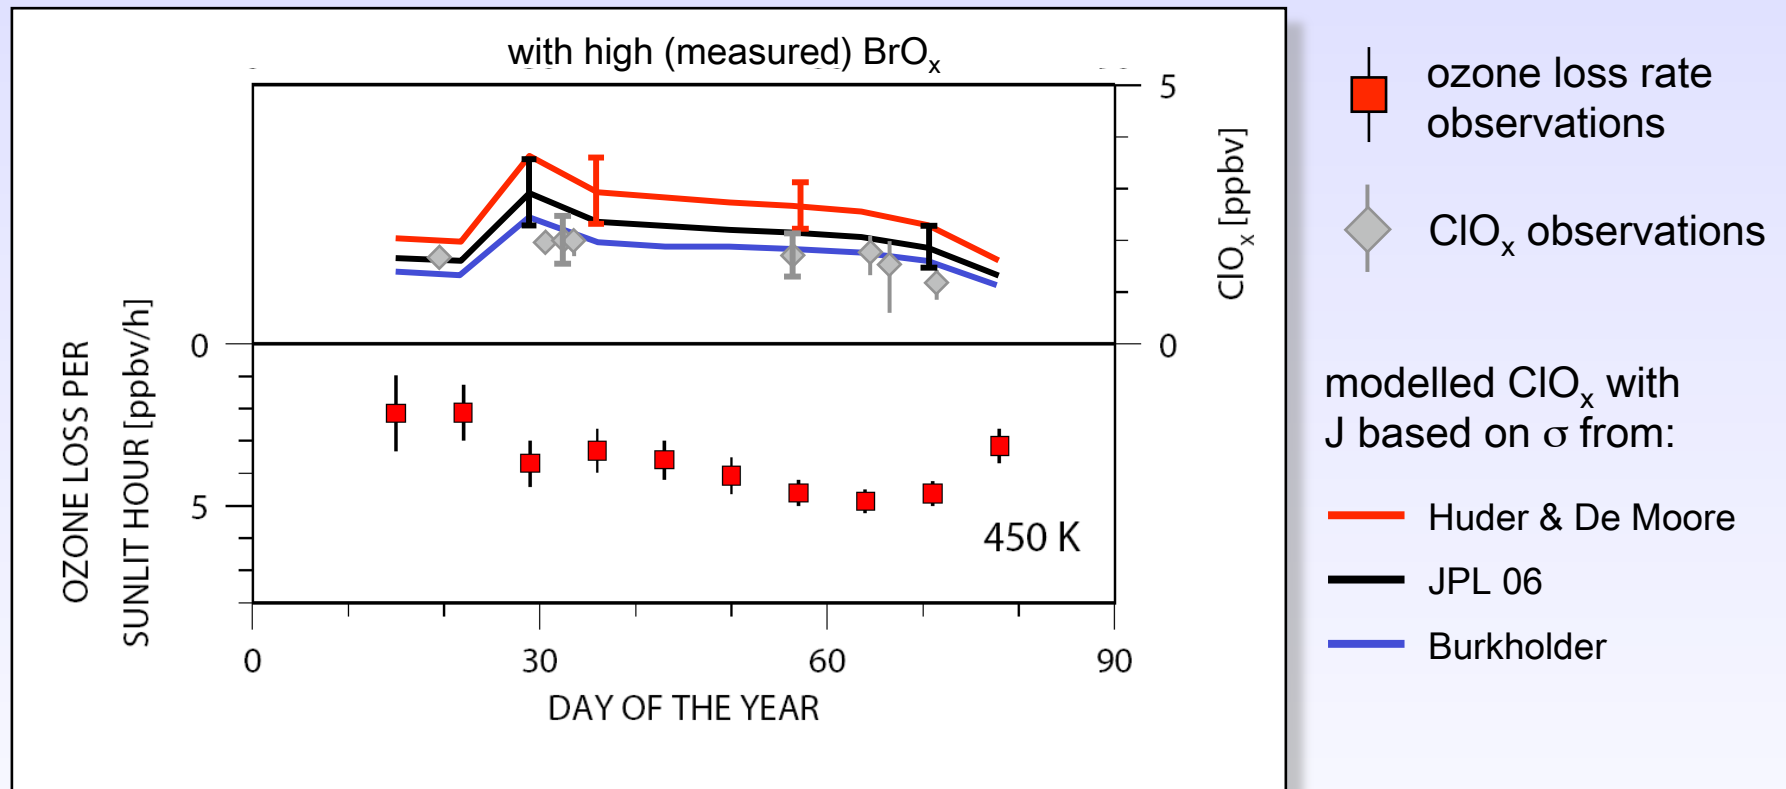

=>

Calculated ozone loss rate drops by more than a factor of two if Pope et al. cross sections are used

# ClO<sub>x</sub> required to reproduce observed ozone loss rates

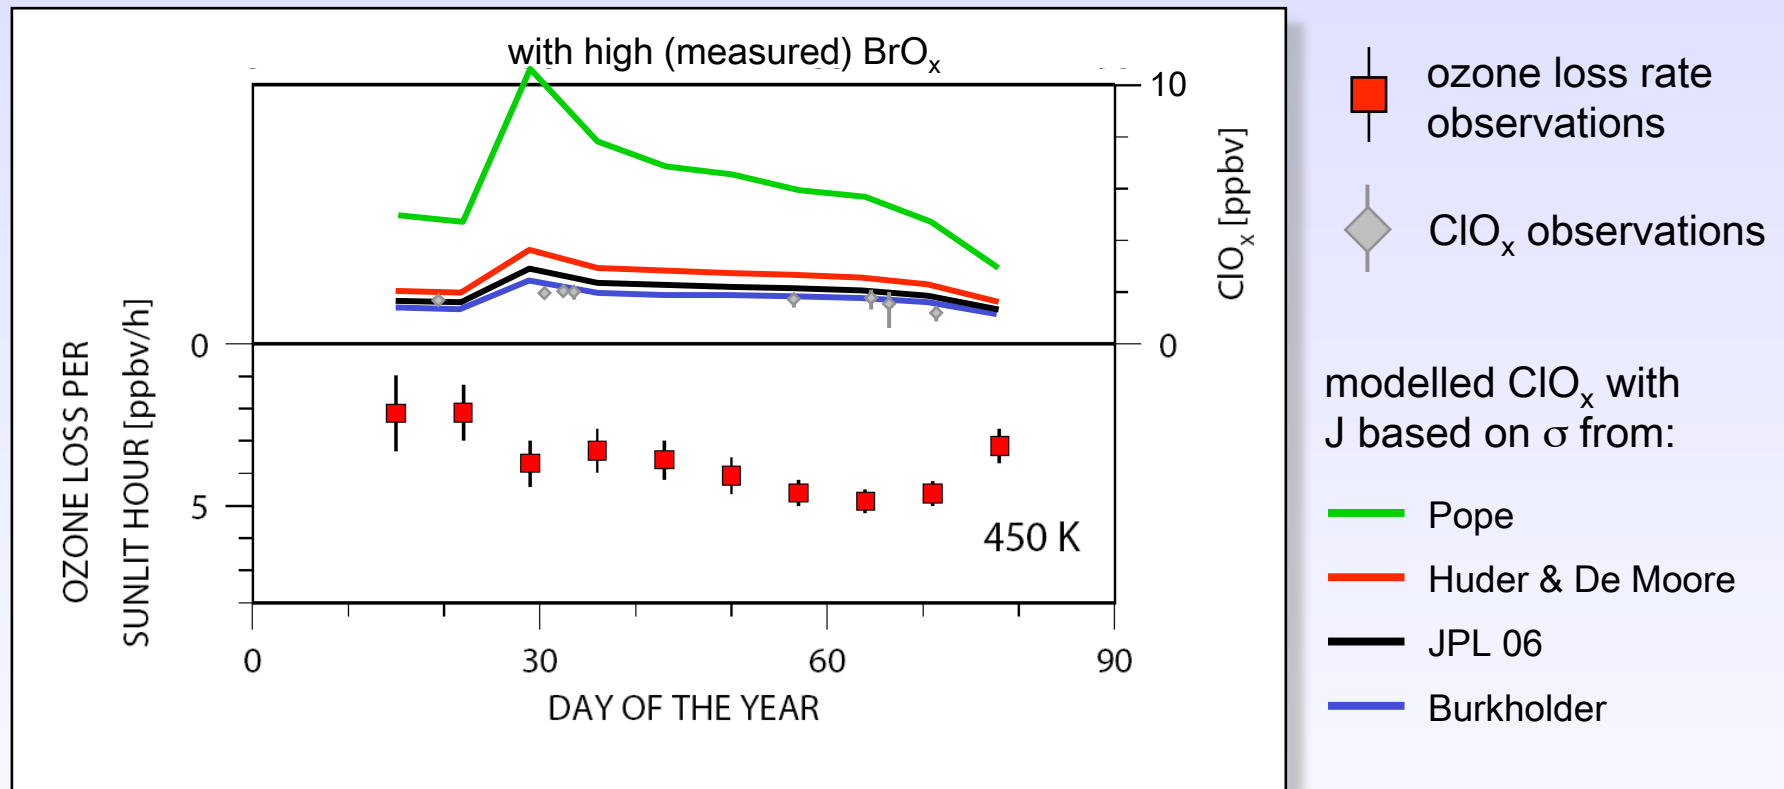

based on model with different assumptions for  $\sigma_{\text{ClOOCl}}$

based on Frieler et al., 2006; WMO 2006

# ClO<sub>x</sub> required to reproduce observed ozone loss rates

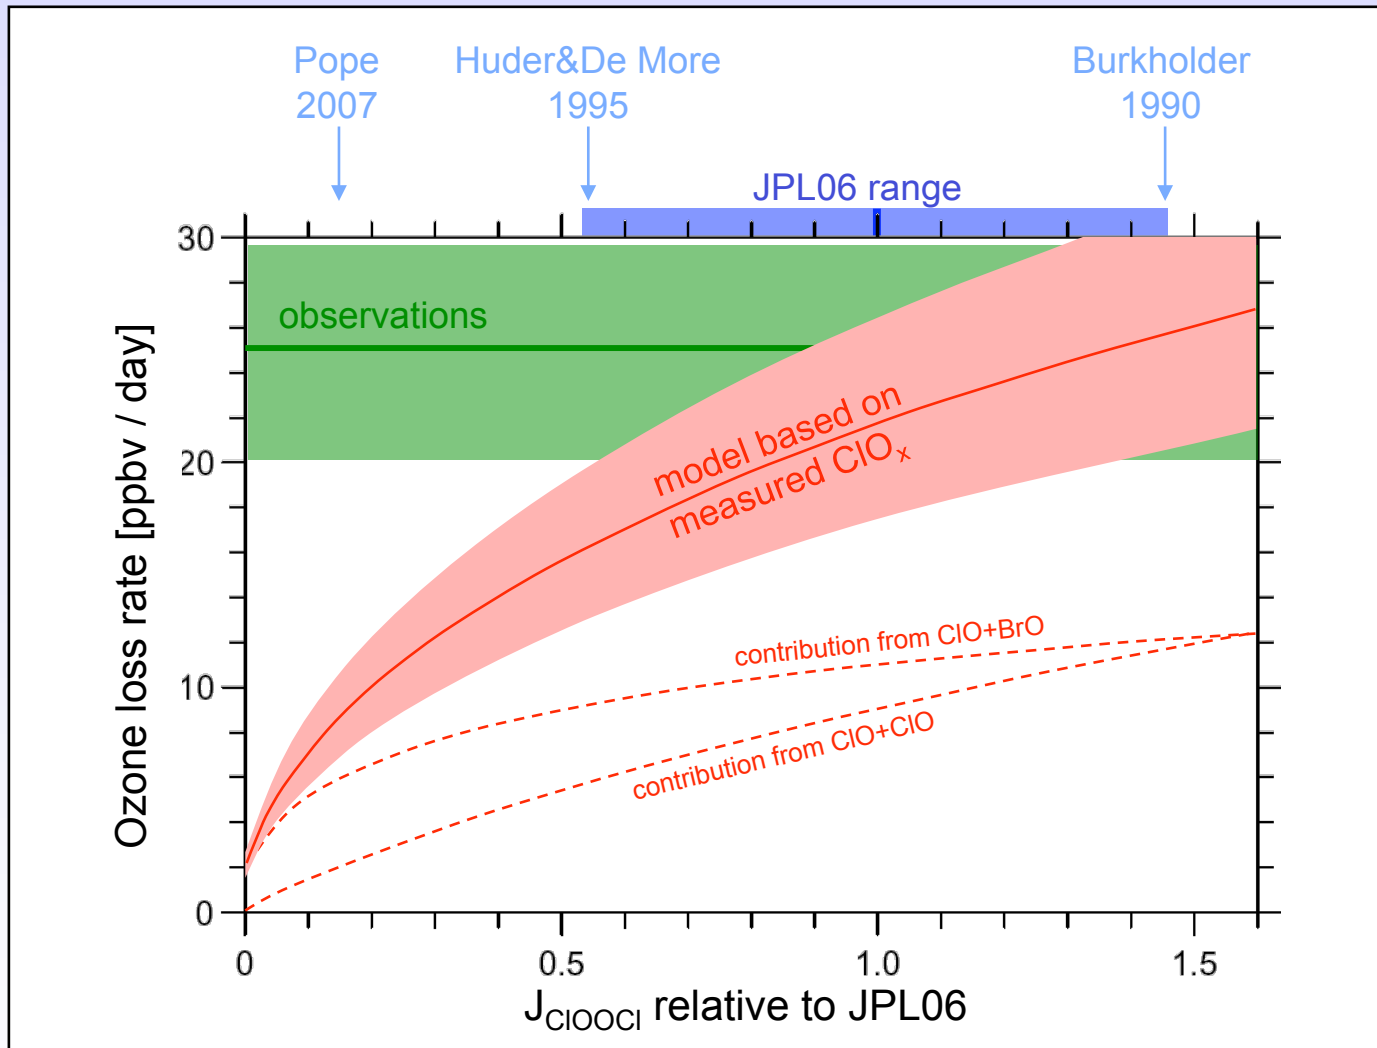

based on model with different assumptions for  $\sigma_{\text{ClOOCl}}$

update of Frieler et al., 2006; WMO 2006

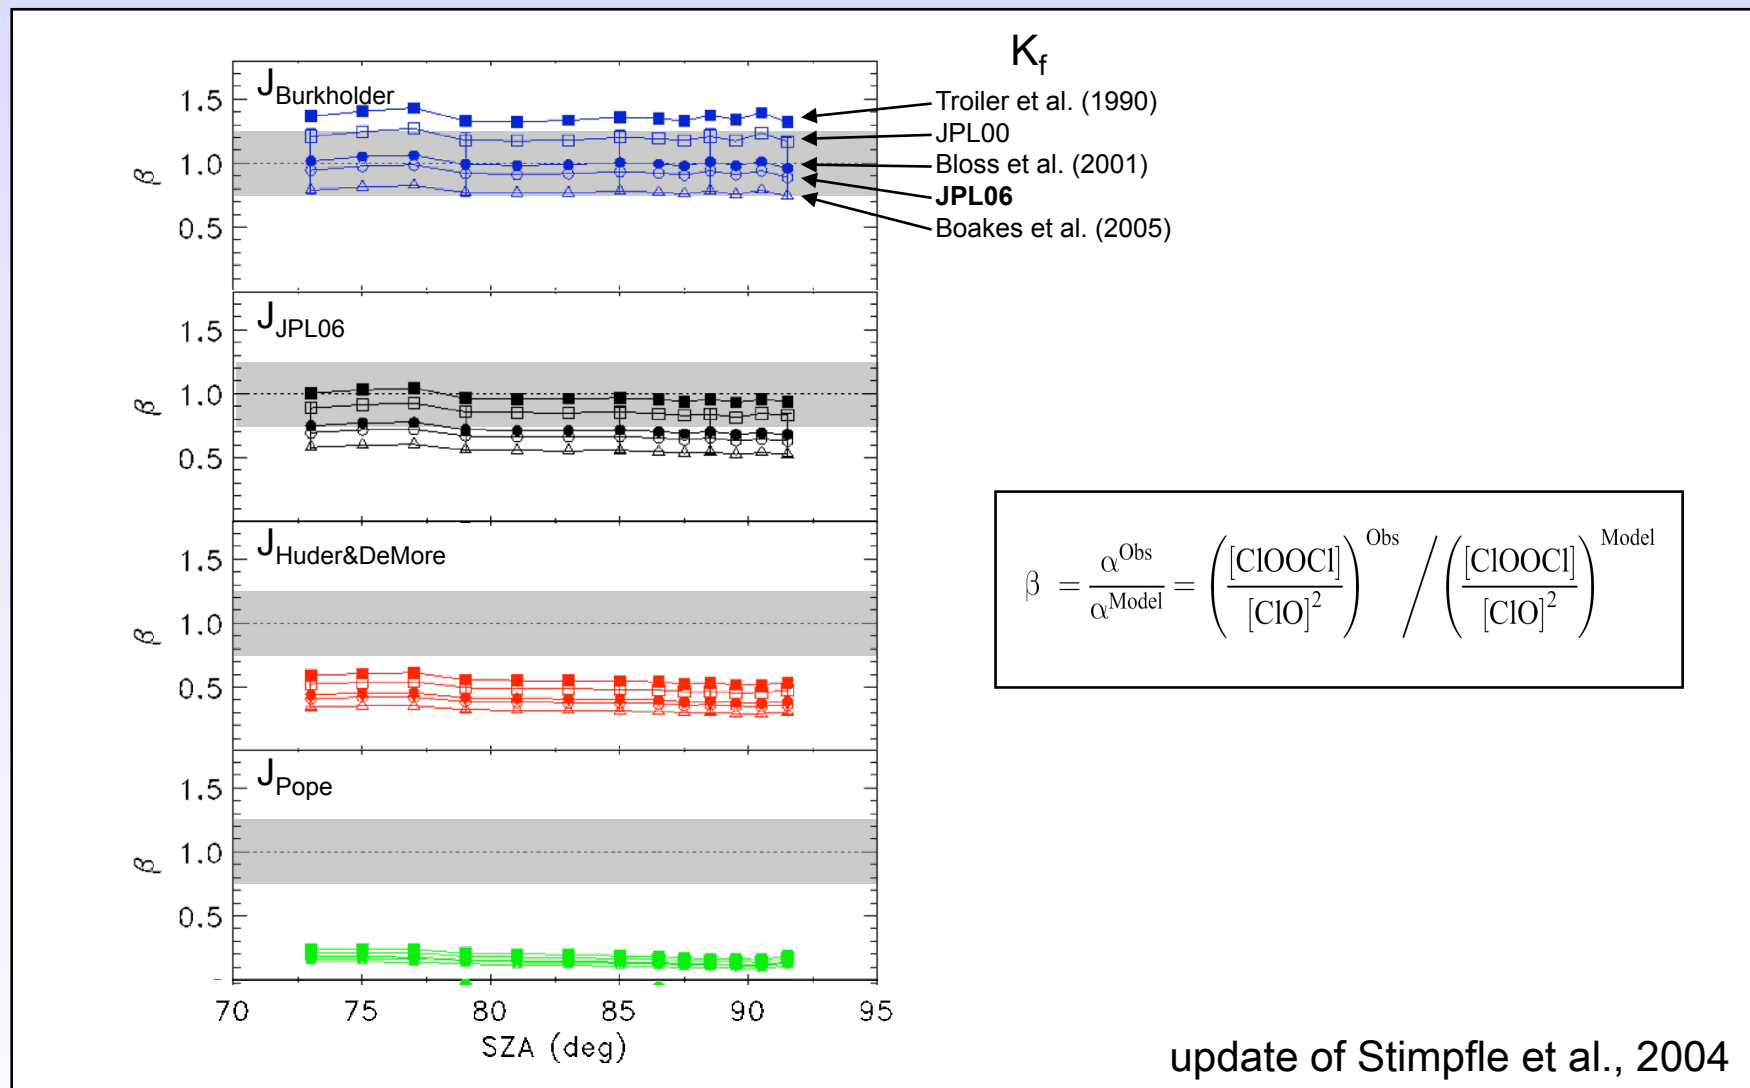

# Overall polar ozone loss rate versus $J_{\text{ClOOCl}}$

model constraint by measurements during SOLVE flight 000202  
ozone loss rates from Match

# Diurnal variation of ClO

## Data from SOLVE 2000

# EUPLEX 2003

## Self-Match flight

January 30, 2003

- Individual air masses probed before and after sunset.
- Success of flight planning confirmed by contrail intersections.
- Sensitivity of  $[ClO]$  on  $k_{eq}$  changes steeply at sunset.

=>

$k_{eq}$  can be derived from measurements of  $[ClO]$  alone, without making assumptions on  $[ClO_x]$  or  $[ClOOCl]$

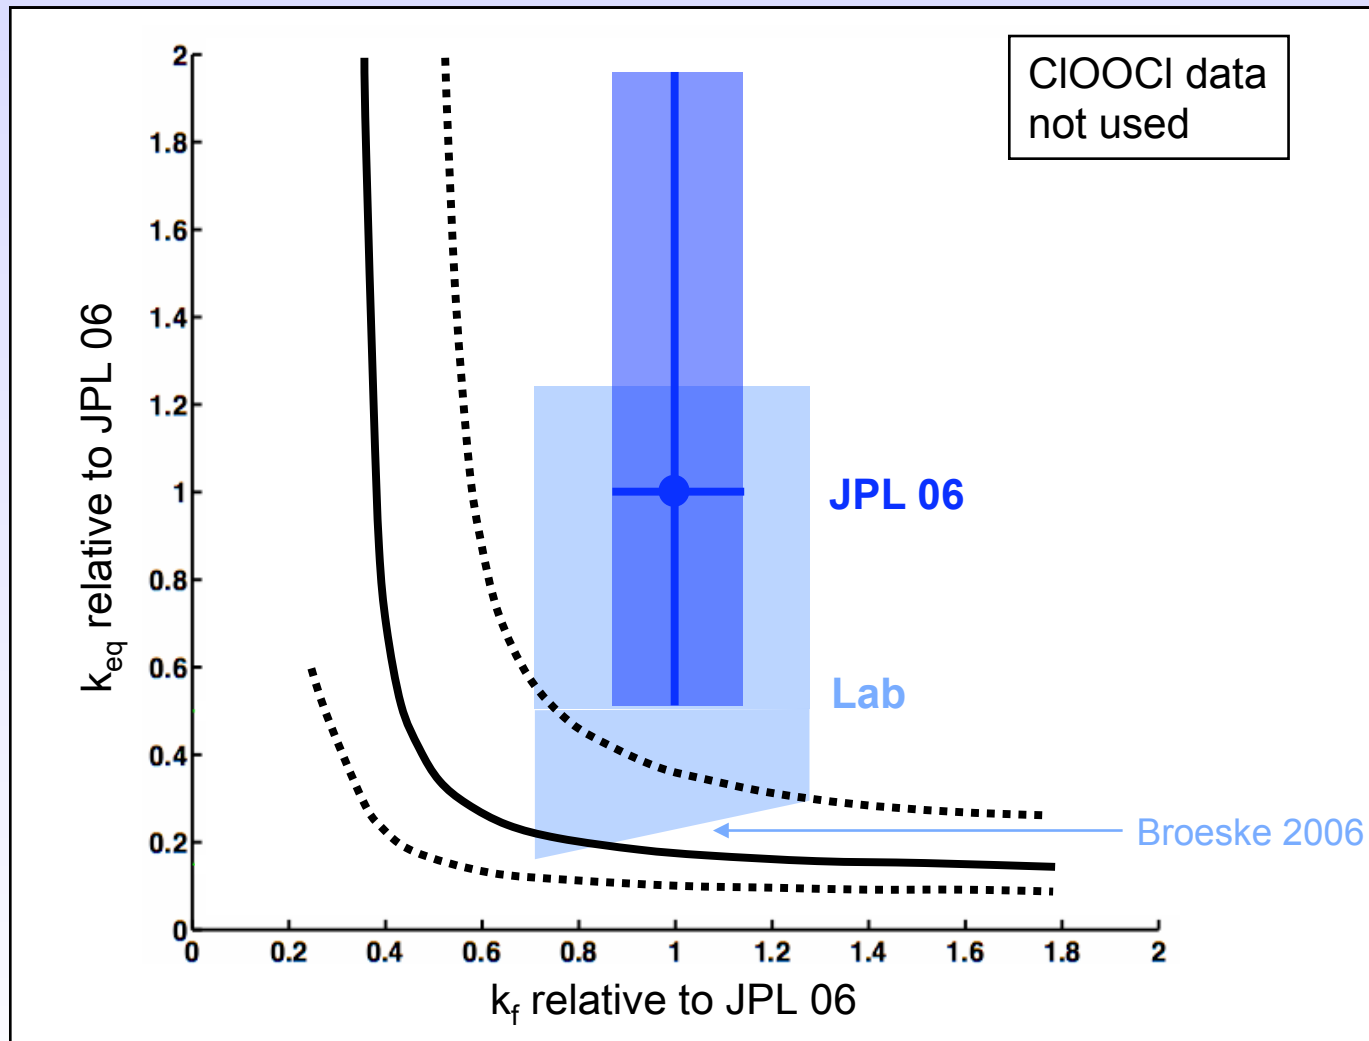

if  $[ClO_x]$  is constrained by measured  $[ClOOCl]$ ,  $J$  can be derived

Schofield et al., 2008

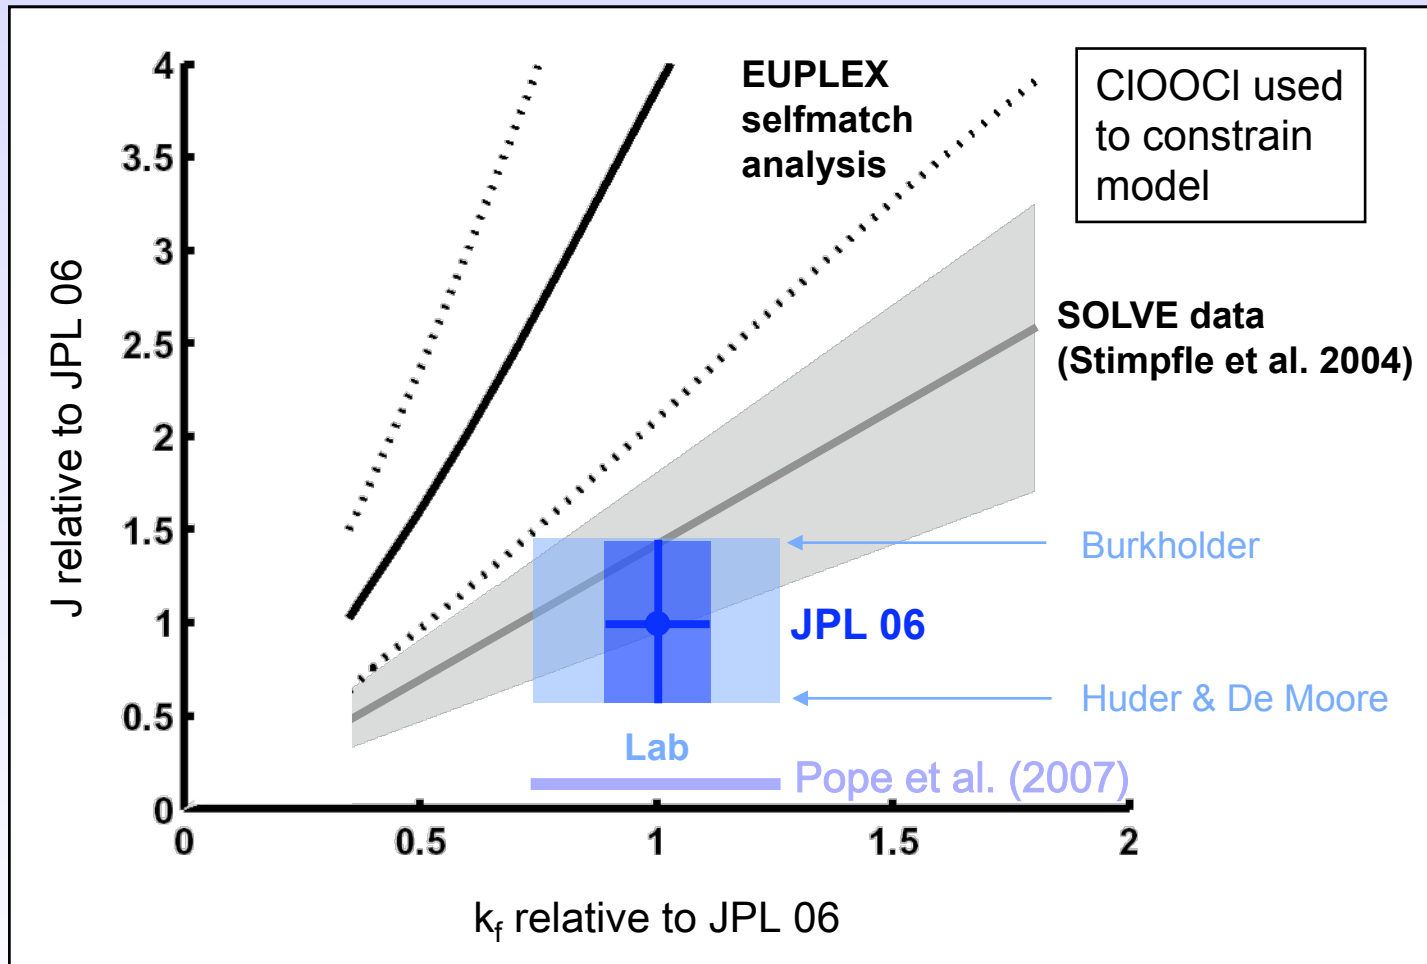

# $k_{eq}$ from EUPLEX self-match flight

Schofield et al., 2008

# J from EUPLEX self-match flight

Schofield et al., 2008

## Atmospheric measurements show that:

- Based on standard chemistry observed ozone loss rates
  - agree best with models that are based on  $J_{\text{Burkholder}}$
  - $J_{\text{JPL06}}$  recommendations are within uncertainty
  - marginal agreement for  $J_{\text{Huder\&DeMore}}$
- If  $J$  is anywhere close to  $J_{\text{Pope}}$ , a large fraction of the observed ozone loss can not be explained by standard chemistry
- If Pope et al. 2007 is correct an unknown mechanism breaks down ClOOCl and is responsible for most of the observed ozone loss

# Daytime loss vs. nighttime loss

Bivariate regression analysis:

Rate of change during darkness

time in darkness

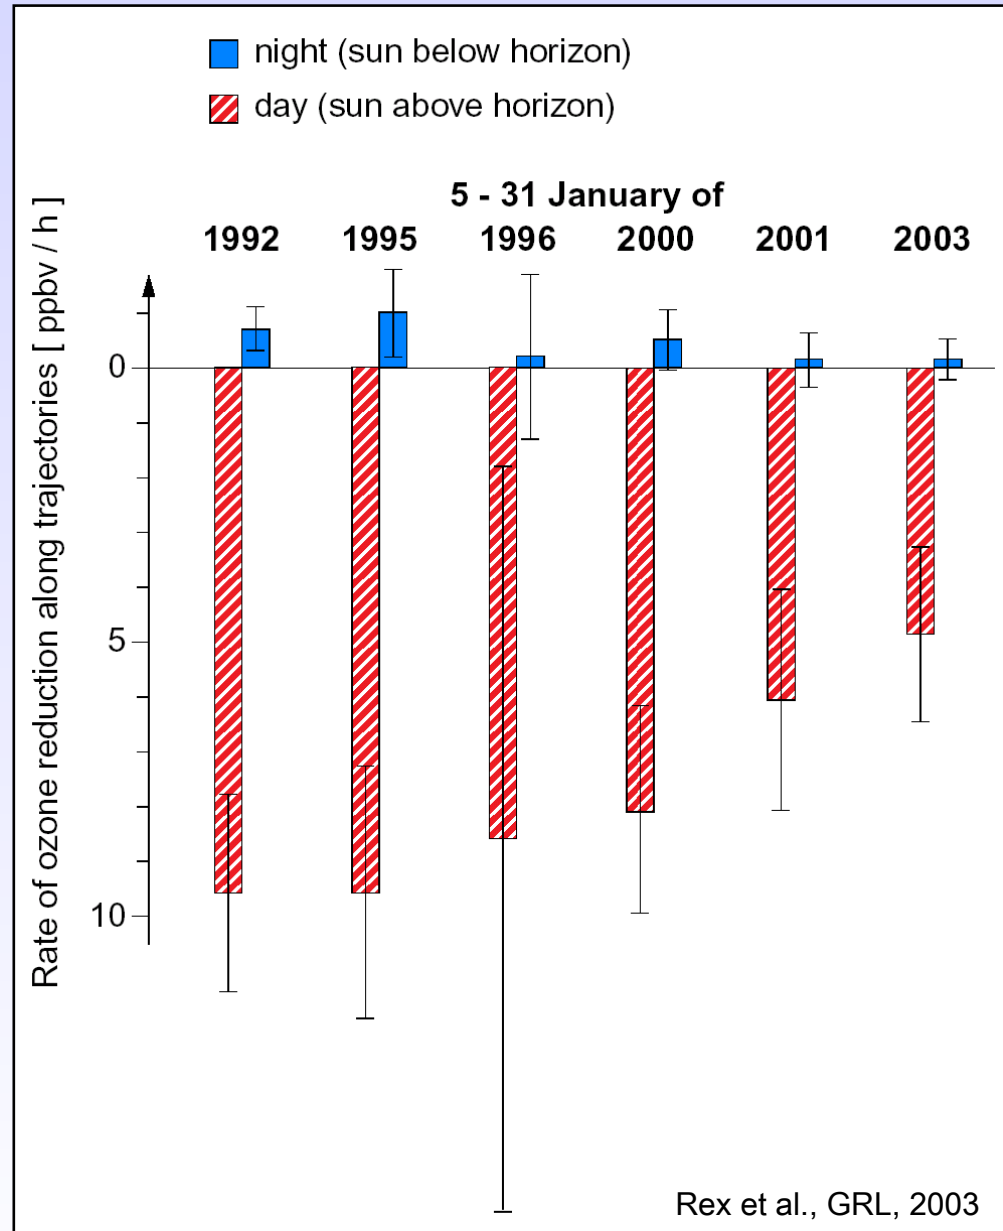

$$\Delta O_3 = L_s \cdot t_s + L_d \cdot t_d$$

Loss rate during sunlit times

sunlit time

=>

- loss of ozone only in sunlight
- no change in darkness

# Relation between ozone loss rate and temperature history

February, data from all years,  $\Theta=450-500\text{K}$

$T_{\min}$  is the minimum temperature encountered during the past ten days (along individual air mass trajectory)

lifetime of  $\text{ClO}_x$  is in the order of 10 days in February

Ozone loss only in air masses that have been exposed to temperatures below 195K

Schulz, Dissertation, 2000

## Constraints for potential mechanisms:

- (1) Daytime ClO production needs to mimic „Burkholder photolysis“ (Stimpfle et al., 2004). This applies to both, am and pm conditions !
- (2) Nighttime source of ClO (based on several observations of ClO during night)
- (3) Ozone loss rates are as calculated with a model using „Burkholder photolysis“ (Frieler et al, 2006)

# Potential mechanisms

Potential mechanisms fall into two categories:

(1) Direct mechanism:

(2) Formation of an unknown nighttime reservoir (Cl~)

## (1) Direct mechanism

- $k \times [\text{X}]$  roughly equals  $J_{\text{Burkholder}}$  for all sza, for am and pm
  - collision rate theory: daytime abundance of  $\text{X} > 10$  pptv
- => BrO and ClO are options
- $\text{X}=\text{ClO}$  is probably not consistent with Bloss et al., 2001
  - $\text{X}=\text{BrO}$  model fails to reproduce diurnal variation of ClO

=> direct mechanism appears to be unlikely

## (2) Formation of an unknown nighttime reservoir (Cl~)

- „efficient photolysis“ similar to Burkholder photolysis:

$$J_{\text{ClOOCl\_Pope}} \times [\text{ClOOCl}] + J_{\text{Cl}\sim} \times [\text{Cl}\sim] = J_{\text{Burkholder}} \times [\text{Cl}_{\text{Harvard}}]$$

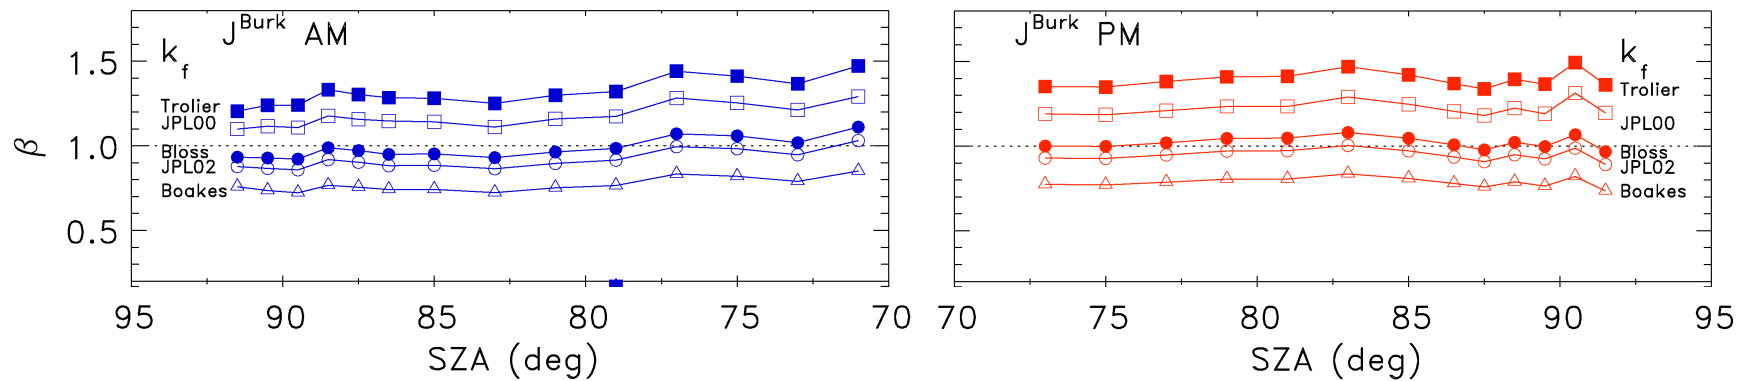

(Cl<sub>Harvard</sub> = total Cl in all species that are seen as ClOOCl in Harvard type instruments, i.e. all species that decompose into ClO at T~370K, without also producing Cl atoms)

# am/pm differences in efficient J ?

measurements during EUROSOLVE/SOLVE 2000  
analysis like in Stimpfle et al.(2004), but am/pm separately

$$\beta = \frac{\alpha^{\text{Obs}}}{\alpha^{\text{Model}}} = \left( \frac{[\text{ClOOC}]}{[\text{ClO}]^2} \right)^{\text{Obs}} / \left( \frac{[\text{ClOOC}]}{[\text{ClO}]^2} \right)^{\text{Model}}$$

=> ClO production rate similar to  $J_{\text{Burkholder}} \times [\text{Cl}_{\text{Havard}}]$  for all sza, for both am and pm

=> slow buildup of unknown nighttime reservoir over night can be ruled out

## (2) Formation of an unknown nighttime reservoir (Cl~)

=> either reaction is rapid and converts all ClOOCl to Cl~

=> or rapid equilibrium between ClOOCl and Cl~

## (2) Formation of an unknown nighttime reservoir (Cl~)

### (2.1) Rapid conversion of ClOOCl into unknown nighttime reservoir Cl~

- ClOOCl does not exist at all; Cl~ is the only nighttime reservoir  
=>  $J_{Cl\sim} = J_{Burkholder}$  (for all sza)  
=> Cl~ is either Cl<sub>2</sub>, Cl<sub>2</sub>O (or Cl<sub>2</sub>O<sub>5</sub>)
- observations of high ClO during warm nights => nighttime source of ClO
- „ClOOCl“ measurements of Harvard type instruments  
=> Cl~ needs to decompose thermally  
=> rules out Cl<sub>2</sub>

=> Cl~ is Cl<sub>2</sub>O (or Cl<sub>2</sub>O<sub>5</sub>)

=> reaction partner X is an odd oxygen species with VMR >> 10pptv

=> X could be O<sub>3</sub> (or N<sub>2</sub>O, HNO<sub>3</sub>)

- gas phase reaction with O<sub>3</sub> is too slow (DeMoore and Tschuikow-Roux, 1990)

=> heterogenous mechanism (EUPLEX: on sulfate !) ?

- surface area densities needed (collision rate theory): 10 μm<sup>2</sup>cm<sup>-3</sup>
- available: ~1 μm<sup>2</sup>cm<sup>-3</sup>

## (2) Formation of an unknown nighttime reservoir (Cl~)

(2.2) Back reaction also exist, ClOOCl and Cl~ coexist close to equilibrium

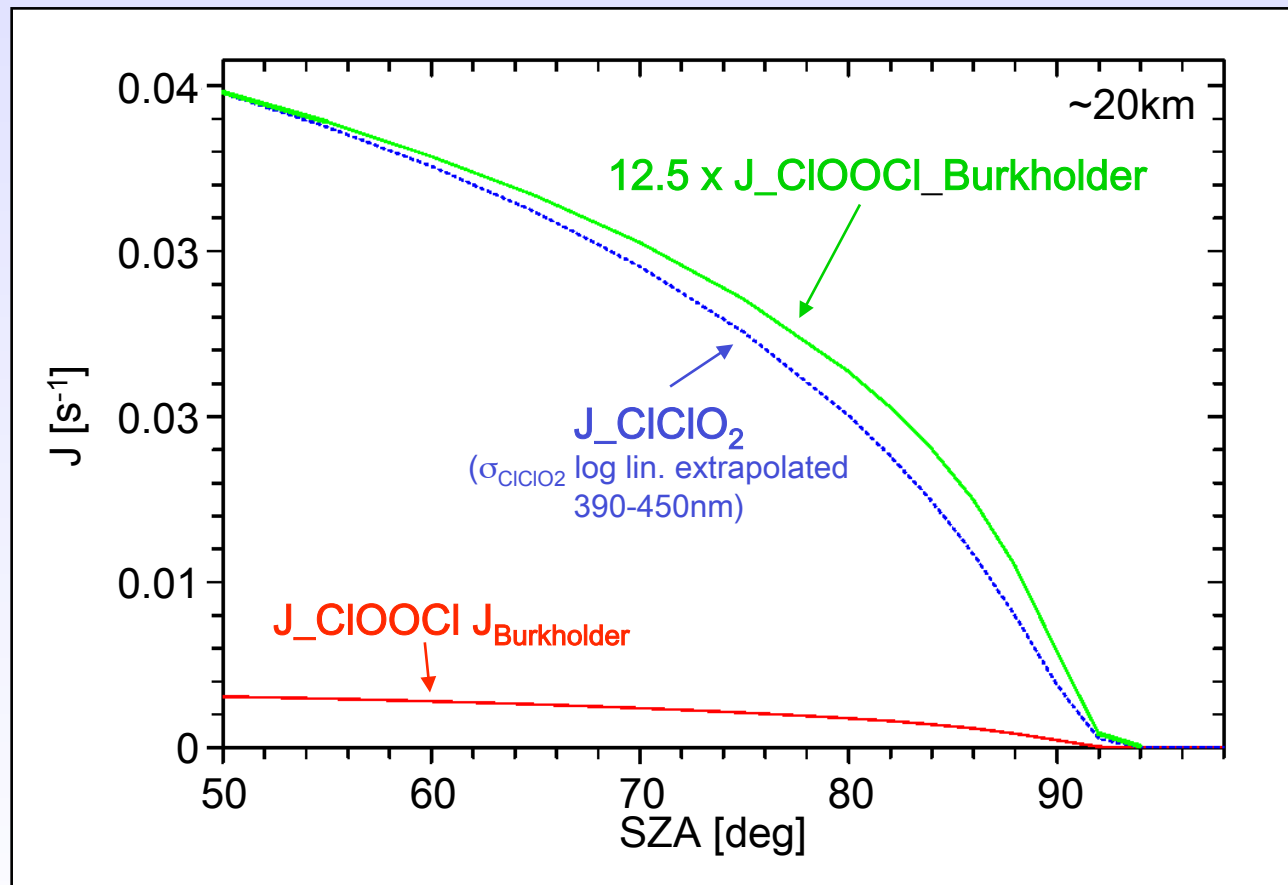

=>  $J_{Cl\sim} \gg J_{Burkholder}$ ; shape of  $J_{Cl\sim}(sza) \sim J_{Burkholder}(sza)$

# Rapid equilibrium between ClOOCl and ClClO<sub>2</sub> ( Cl-Cl(O)O )?

ClOOCl  $\rightleftharpoons$  ClClO<sub>2</sub> barrier too high

e.g. by: ClOOCl + ClO  $\rightarrow$  ClClO<sub>2</sub> + ClO  
 ClClO<sub>2</sub> + ClO  $\rightarrow$  ClOOCl + ClO

=>

~10% of Cl<sub>2</sub>O<sub>2</sub>  
 in the form of ClClO<sub>2</sub>  
 leads to „Burkholder  
 like“ photolysis of the  
 mixture

Temperature  
 dependend equilibrium  
 could explain SOLVE /  
 EUPLEX differences in  
 efficient J and  $k_{\text{eq}}$

## CIO and ClOOCl observations

Model that

- is based on  $J_{\text{ClOOCl}}$  from Pope et al.
- and includes the „ClClO<sub>2</sub>-mechanism“

reproduces all available observations of ClO and ClOOCl. It even reproduces the SOLVE / EUPLEX differences, that are hard to resolve with a model based on standard chemistry

**But !**

- To explain observed ozone loss photolysis of ClClO<sub>2</sub> would have to restore the O-O bond !
- **New upper limits for the abundance of ClClO<sub>2</sub> in the atmosphere are an order of magnitude to low (Jucks et al. in preparation, limit derived from Stimpfle et al., 2004)**

# Conclusions

- Uncertainties in  $J_{\text{ClOOC}l}$  limit our ability to model polar ozone loss quantitatively
  - Based on JPL06 uncertainties (i.e. even without considering Pope et al., 2007), modeled ozone loss rates have up to a factor of three uncertainty.
- If Pope et al. (2007) is correct:
  - An unknown breakdown mechanism for ClOOC $l$  exists
  - Most of the observed ozone loss is due to this unknown mechanism
- It is extremely hard to reconcile Pope et al. (2007) with atmospheric measurements
  - Mechanism has to mimic photolysis according to Burkholder et al. cross sections.
  - Most potential mechanisms are not consistent with in-situ data of ClO, observed ozone loss rates or lab studies.
- New lab measurements of the ClOOC $l$  cross section needed to resolve this issue (several under way)
- SPARC initiative on chlorine chemistry (led by M. Kurylo and B.-M. Sinnhuber). Info: <https://sparchpo.icg.kfa-juelich.de/SPARCHPO>

**END**

# Conclusions

- **Uncertainties in  $J_{\text{ClOOC}_l}$  limit our ability to model polar ozone loss quantitatively**

Based on JPL06 uncertainties (i.e. even without considering Pope et al., 2007), modeled ozone loss rates have up to a factor of three uncertainty.

- **Based on standard chemistry observed ozone loss rates:**

- agree best with models that are based on  $J_{\text{Burkholder}}$
- $J_{\text{JPL06}}$  recommendations are within uncertainty
- $J_{\text{Huder\&De Moore}}$  would require to push all uncertainties to the limits

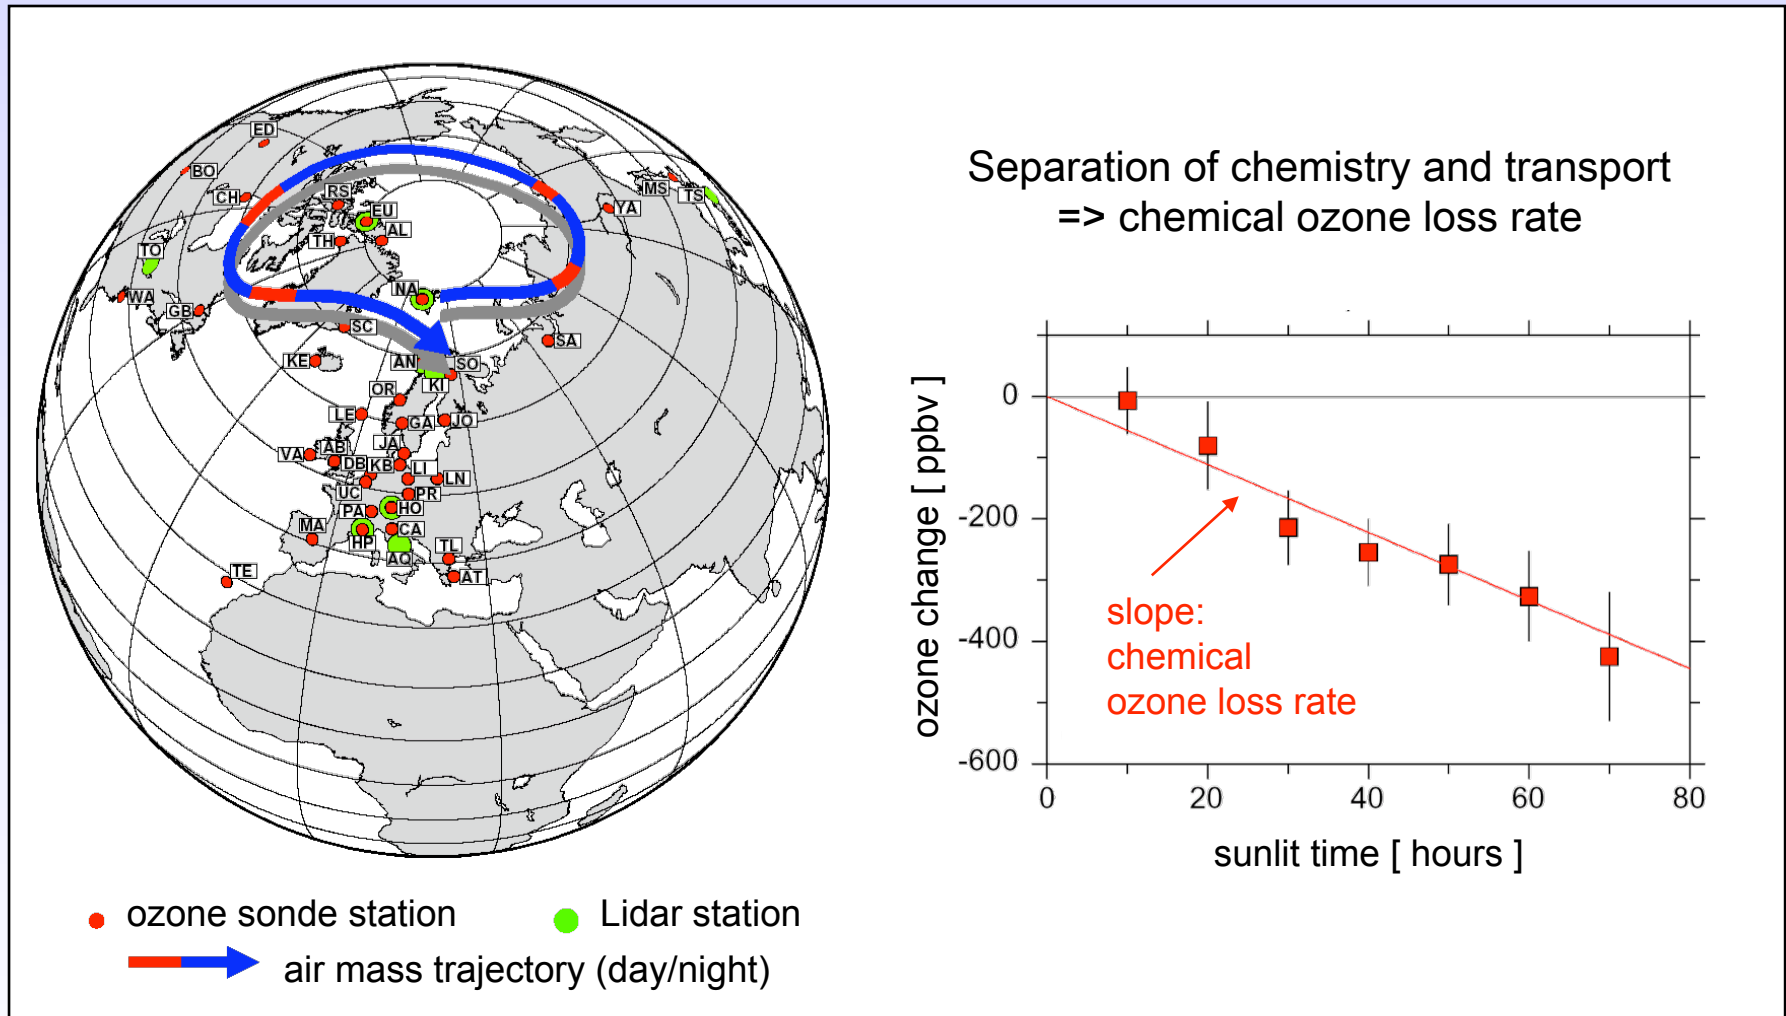

- **If  $J$  is anywhere close to  $J_{\text{Pope}}$ , a large fraction of the observed ozone loss can not be explained by standard chemistry**

- **Ozone loss occurs only in sunlight**

- **Ozone loss occurs only in air masses that have been exposed to temperatures below 195K**

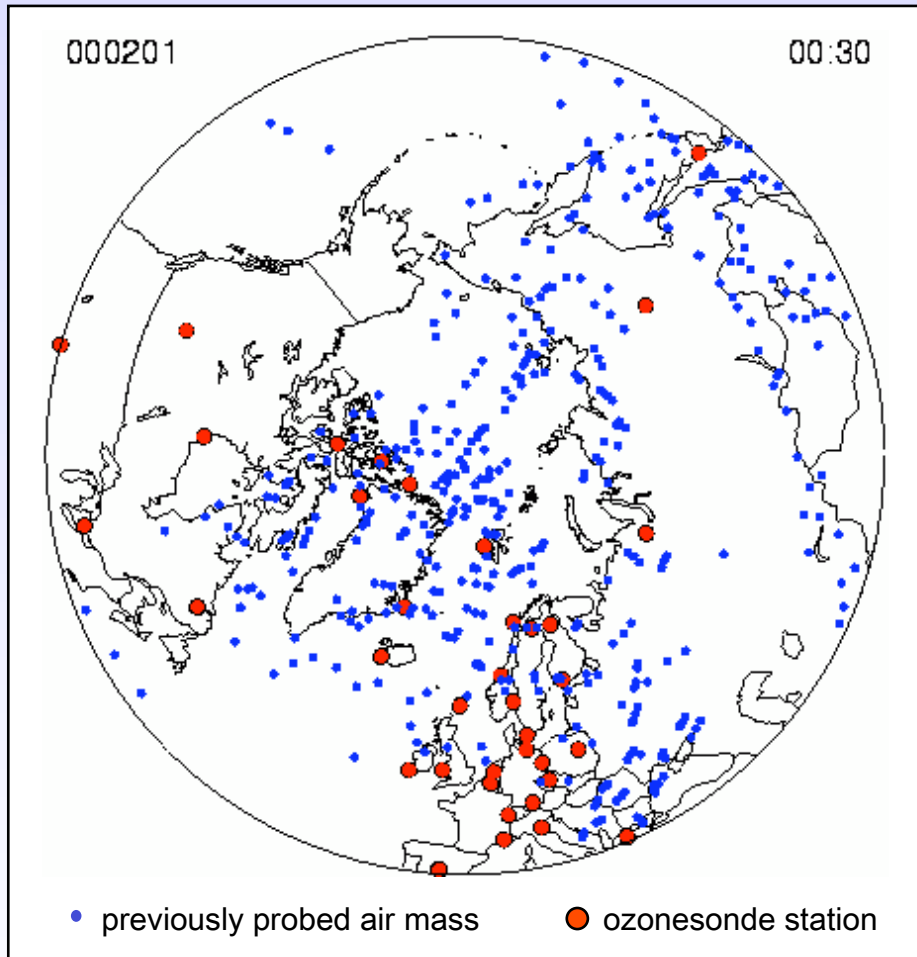

# The Match Project

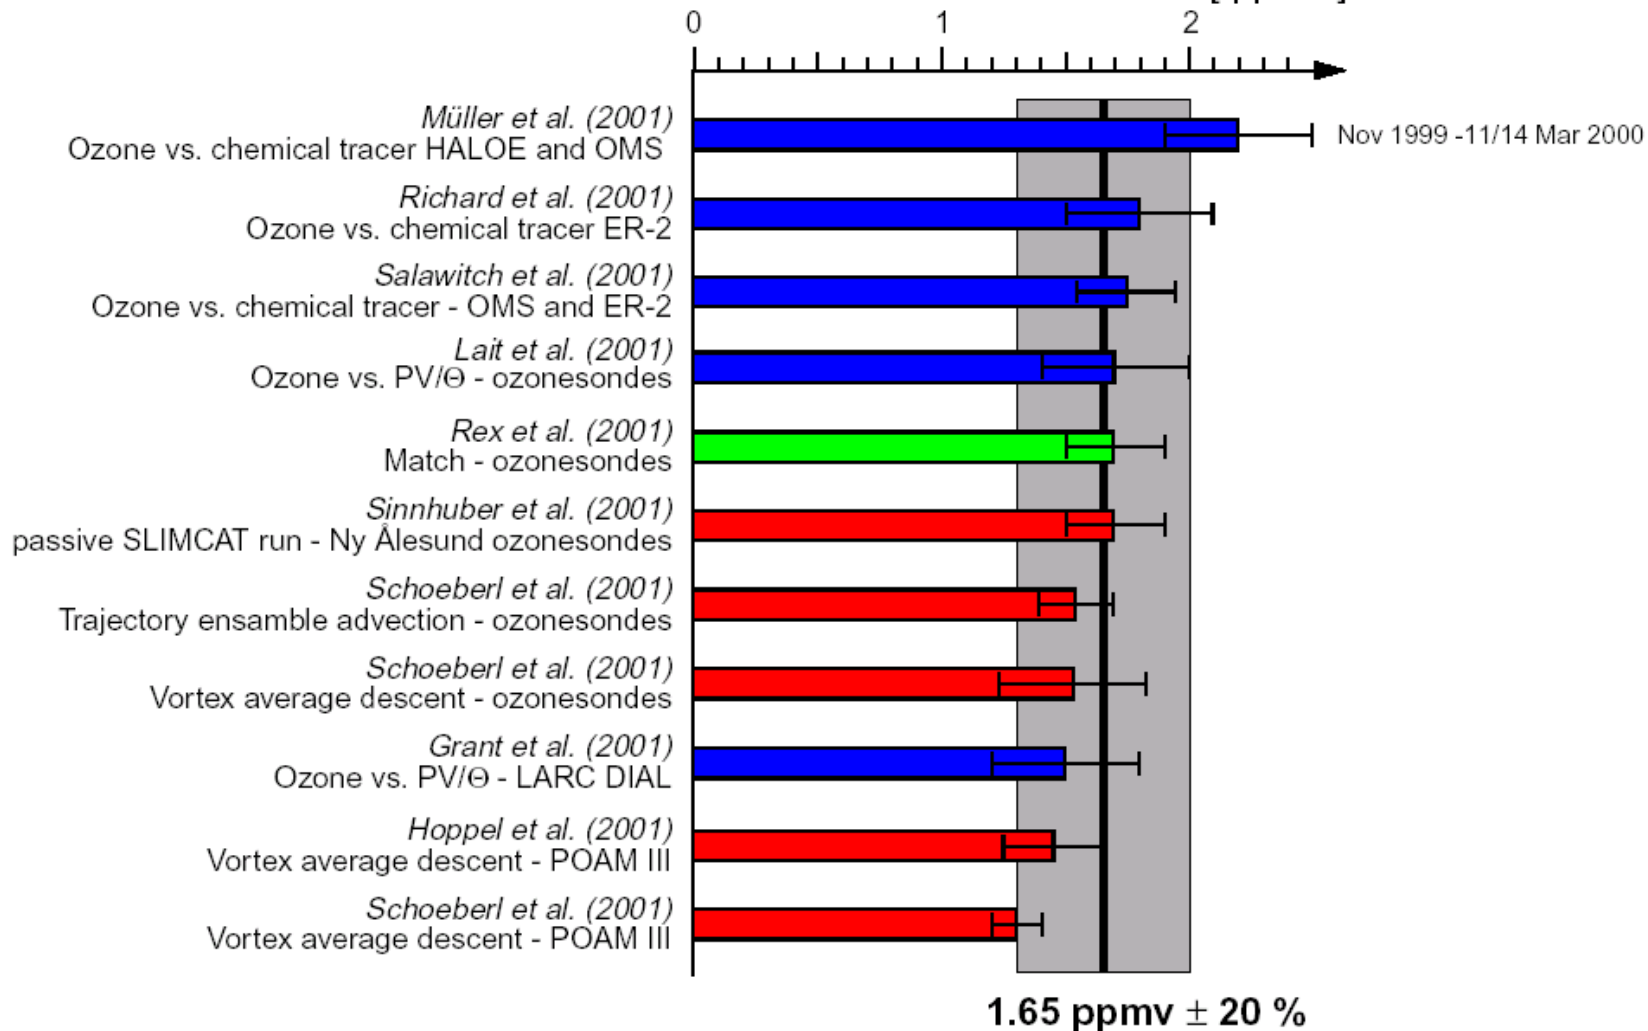

e.g. Rex, 1993; von der Gathen et al., Nature, 1995; Rex et al., Nature, 1997

## Match campaigns

- 35 stations
- ~500-1200 ozonesondes per winter
- >1000 match events per winter
- 11 Arctic and 2 Antarctic campaigns since the early 90ies (EU + natl. funding)

### Ozone loss at 450 K between 20 Jan and 12 Mar [ ppmv ]

based on Newman et al., JGR, 2002

## Results from measurements of ClO / ClOOCl

all values relative to JPL-06  
estimates are based on known chemistry

- $k_{eq}$ 
  - SOLVE:  $k_{eq} = 50\%$  best fit
  - EUPLEX self-match:  $k_{eq} = 20\%$  best fit;  $k_{eq} \leq 40\%$
- J
  - SOLVE:  $J = 150\%$  best fit;  $J \geq 75\%$
  - EUPLEX self match:  $J \gg 200\%$  best fit
  - Pope et al.:  $J = 16\%$  (~ 9 times smaller than in-situ suggests)

=>

- No overlap between uncertainties from in-situ estimates of J and Pope et al.
- Discrepancies appear to be larger for warmer conditions

# Potential solutions: (1) Direct mechanism

## Breakdown of ClOOCl directly recycles Cl:

Collision rate theory and diurnal  
variation:  $\text{X} = \text{BrO}$

Thermodynamically only  
 $\text{ClOOCl} + \text{BrO} \rightarrow \text{ClOO} + \text{BrOCl}$   
can occur

Thermal decomposition of BrOCl  
has to be rapid to prevent loss of  
bromine to BrOCl

Model that includes this mechanism does not reproduce diurnal variation of ClO

**Not likely**

# Potential solutions: (2) Indirect mechanism

=>  $J_{\text{ClOOCl}} \times [\text{ClOOCl}] + J_{\text{Cl}\sim} \times [\text{Cl}\sim]$  similar to "Burkholder rate"

~~Cl~ could be: ClO, Cl<sub>2</sub>, Cl<sub>2</sub>O, ClOClO, ClClO<sub>2</sub>,~~

~~Cl<sub>2</sub>O<sub>3</sub>, Cl<sub>2</sub>O<sub>4</sub>, Cl<sub>2</sub>O<sub>5</sub>, Cl<sub>2</sub>O<sub>6</sub>, Cl<sub>2</sub>O<sub>7</sub>~~

(2.1)

reaction is slow <sup>(1)</sup>

=> Cl~ and ClOOCl coexist

=> ratio Cl~/ClOOCl goes up over night

=> am/pm differences in  $J_{\text{Cl}\sim+\text{ClOOCl}}$  (sza)

**in contrast to in-situ data**

(2.2)

Reaction is fast <sup>(2)</sup>

=> Cl~ is the only reservoir

=>

(1)  $J_{\text{Cl}\sim}$  similar to  $J_{\text{ClOOCl, Burkholder}}$   
=> Cl~: Cl<sub>2</sub>, Cl<sub>2</sub>O, (ClOClO, Cl<sub>2</sub>O<sub>5</sub>)

(2) Cl~ decomposes thermally  
=> Cl~: Cl<sub>2</sub>O, (ClOClO, Cl<sub>2</sub>O<sub>5</sub>)

(2.3)

reaction

Cl~ + Y -> ClOOCl + X

also exists, i.e.

Cl~ and ClOOCl

coexist in equilibrium

=>

$J_{\text{Cl}\sim}$  much larger than

$J_{\text{ClOOCl, Burkholder}}$

=> Cl~: ClClO<sub>2</sub>,  
(ClOClO, Cl<sub>2</sub>O<sub>5</sub>)

(2.3.1)  
Cl~ is ClClO<sub>2</sub>  
(or ClOClO)

=>

X, Y are any M,  
ClO or ClOOCl

**possible,  
but photolysis  
would need to restore  
the O-O bond**

(2.2.1)

Cl~ isn't odd oxygen

Cl~: ClOClO

**$J_{\text{ClOClO}}$  similar to  
 $J_{\text{ClOOCl, Burkholder}}$  ?  
unlikely**

(2.2.2.1)  
gas phase reaction

**too slow (DeMoore and  
Tschuikow-Roux, 1990)**

(2.2.2)

Cl~ is odd oxygen

Cl~: Cl<sub>2</sub>O or Cl<sub>2</sub>O<sub>5</sub>

=> X is odd oxygen

=> X is O<sub>3</sub>

=>  $k \geq 10^{-15}$

(2.2.2.2)  
heterogenous reaction  
=> must occur on sulfate

**surface area dens. not sufficient**

## Potential solutions (2)

### (2.1) ClOOCl does not exist at all; Cl~ is the only nighttime reservoir

$$\Rightarrow J_{\text{Cl}\sim} = J_{\text{Burkholder}}$$

$$\Rightarrow \text{Cl}\sim = \text{Cl}_2\text{O (or Cl}_2\text{O}_5), X = \text{O}_3$$

$\Rightarrow$  gas phase reaction too slow (DeMoore and Tschuikow-Roux, 1990)

heterogenous mechanism (EUPLEX: on sulfate !)

$\Rightarrow$  surface area densities needed (collision rate theory):  $10\mu\text{m}^2\text{cm}^{-3}$

$\Rightarrow$  available:  $\sim 1\mu\text{m}^2\text{cm}^{-3}$

### (2.2) Back reaction also exist, ClOOCl and Cl~ coexist close to equilibrium

$$\Rightarrow J_{\text{Cl}\sim} > J_{\text{Burkholder}}; J_{\text{Cl}\sim}(\text{sza}) \sim J_{\text{Burkholder}}(\text{sza})$$

$$\Rightarrow \text{Cl}\sim = \text{ClClO}_2 \text{ !?}$$

Formation e.g. by reaction  $\text{ClOOCl} + \text{ClO}$  or  $\text{ClOOCl} + \text{ClOOCl}$

$\Rightarrow$  to explain observed ozone loss photolysis of  $\text{ClClO}_2$ , would have to restore the O-O bond !

## Research needs

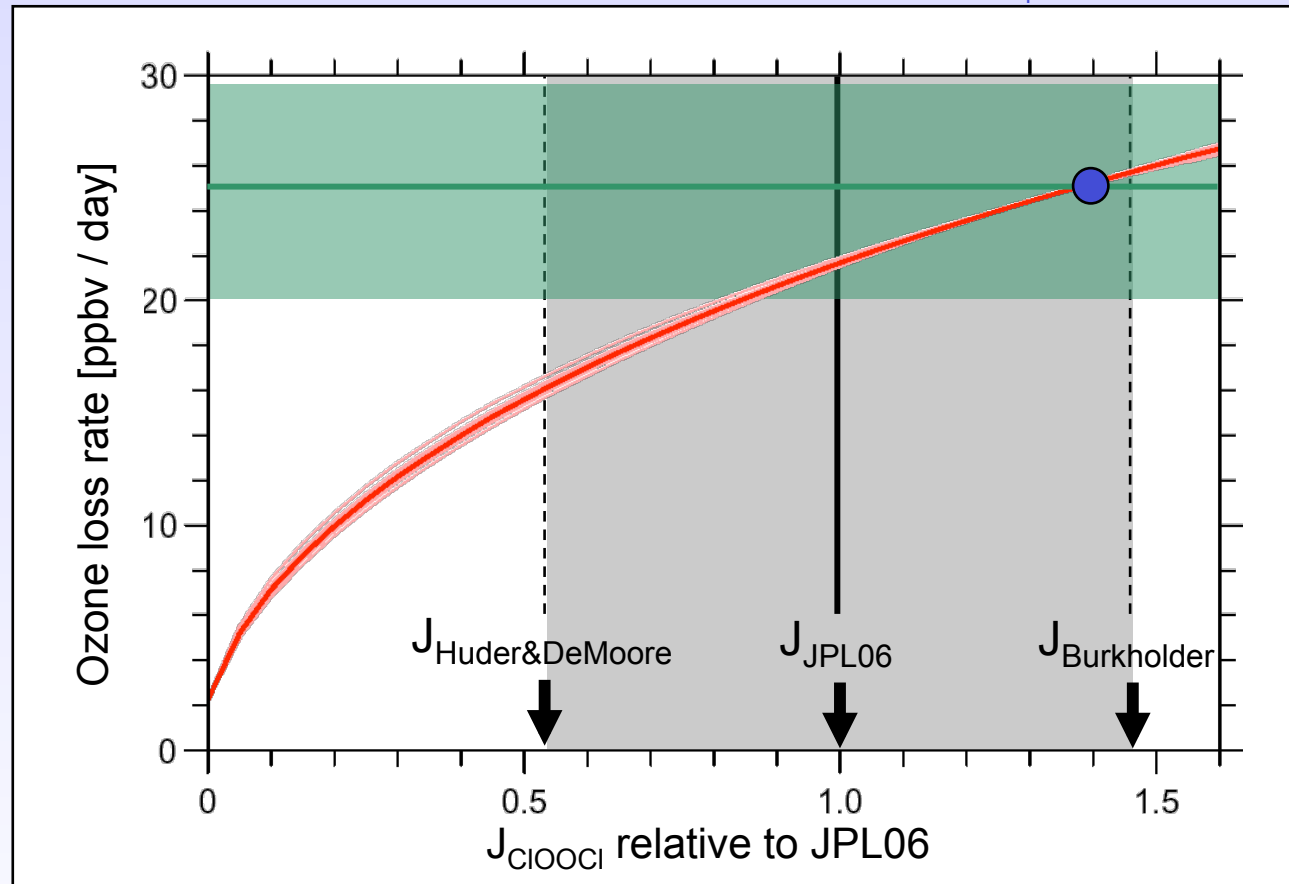

- Verify Pope et al. (2007) results in the lab
- Measure ClOOCl cross sections in O<sub>2</sub> atmosphere
- Identify photolysis products of ClClO<sub>2</sub>, ClOClO (lab and ab initio calculations)
- Measure IR/microwave spectra of ClClO<sub>2</sub> and ClOClO and look for features of these species in existing IR/microwave data sets.
- Study dynamics of ClO/ClOOCl system in-situ, preferably with match flight patterns extending from local noon to late night and including am and pm measurements.

# Overall polar ozone loss rate versus $J_{\text{ClOOC1}}$

measurements during EUROSOLVE/SOLVE 2000

flight 000202,  $\text{sza} = 82.5^\circ$ , pm, little sensitivity on  $k_{\text{eq}}$  and  $k_f$

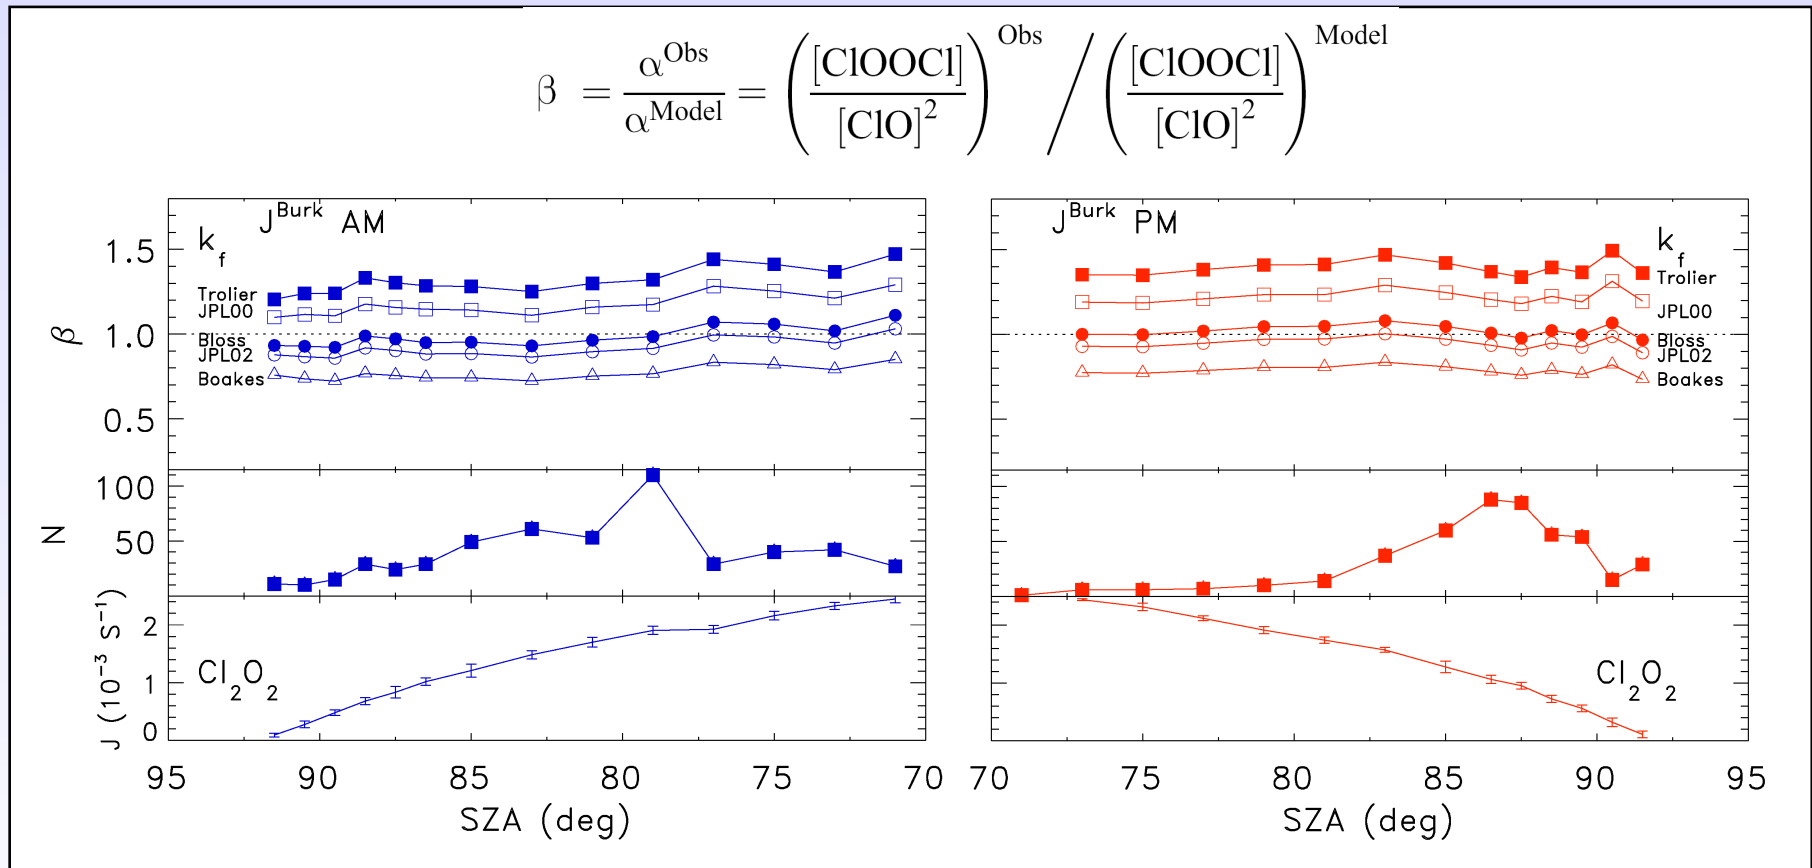

=> model based on  $J_{\text{Burkholder}}$  reproduces observed loss rate

# am/pm differences in efficient J ?

## measurements during EUROSOLVE/SOLVE 2000

$$\beta = \frac{\alpha^{\text{Obs}}}{\alpha^{\text{Model}}} = \left( \frac{[\text{ClOOC1}]}{[\text{ClO}]^2} \right)^{\text{Obs}} / \left( \frac{[\text{ClOOC1}]}{[\text{ClO}]^2} \right)^{\text{Model}}$$

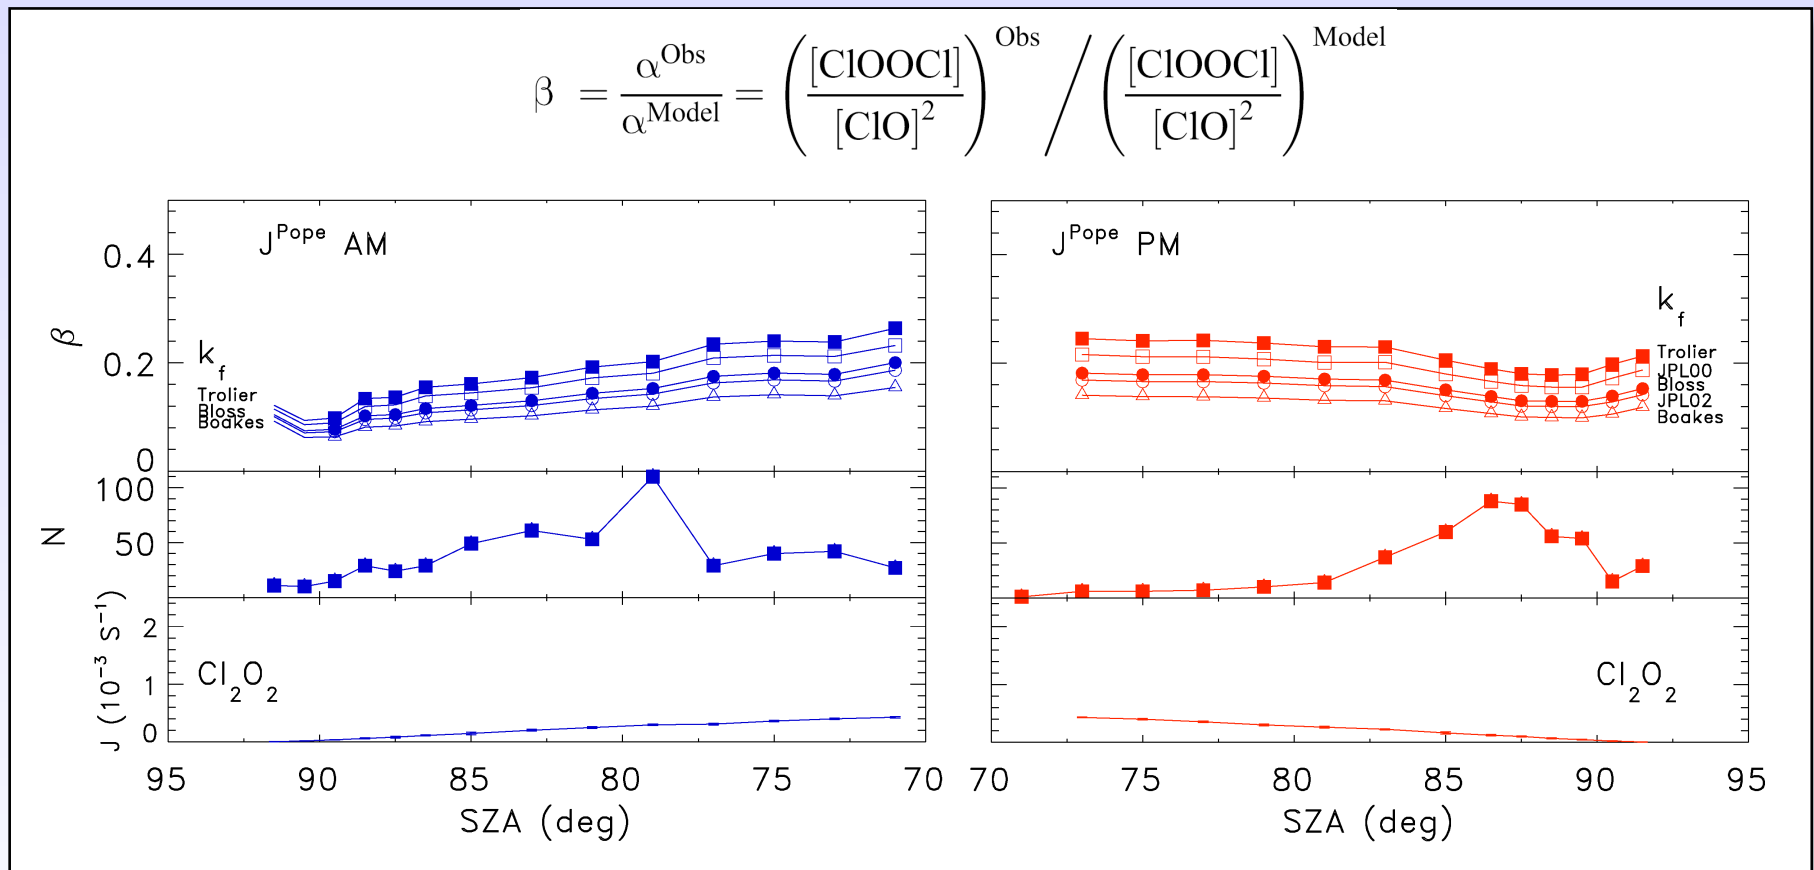

**=> no significant am/pm difference in efficient J**

# J<sub>Pope</sub> and SOLVE data

## measurements during EUROSOLVE/SOLVE 2000

$$\beta = \frac{\alpha^{\text{Obs}}}{\alpha^{\text{Model}}} = \left( \frac{[\text{ClOOC}]}{[\text{ClO}]^2} \right)^{\text{Obs}} / \left( \frac{[\text{ClOOC}]}{[\text{ClO}]^2} \right)^{\text{Model}}$$

**=> J<sub>Pope</sub> is not consistent with data and known chemistry**

# Theoretical understanding of loss process

measurements of  $\text{ClO}_x$  ( $\text{ClO} + 2\text{Cl}_2\text{O}_2$ ) during EUROSOLVE/SOLVE 2000

Frieler et al., GRL 2006; WMO 2006

# Theoretical understanding of loss process

measurements of  $\text{ClO}_x$  ( $\text{ClO} + 2\text{Cl}_2\text{O}_2$ ) during EUROSOLVE/SOLVE 2000

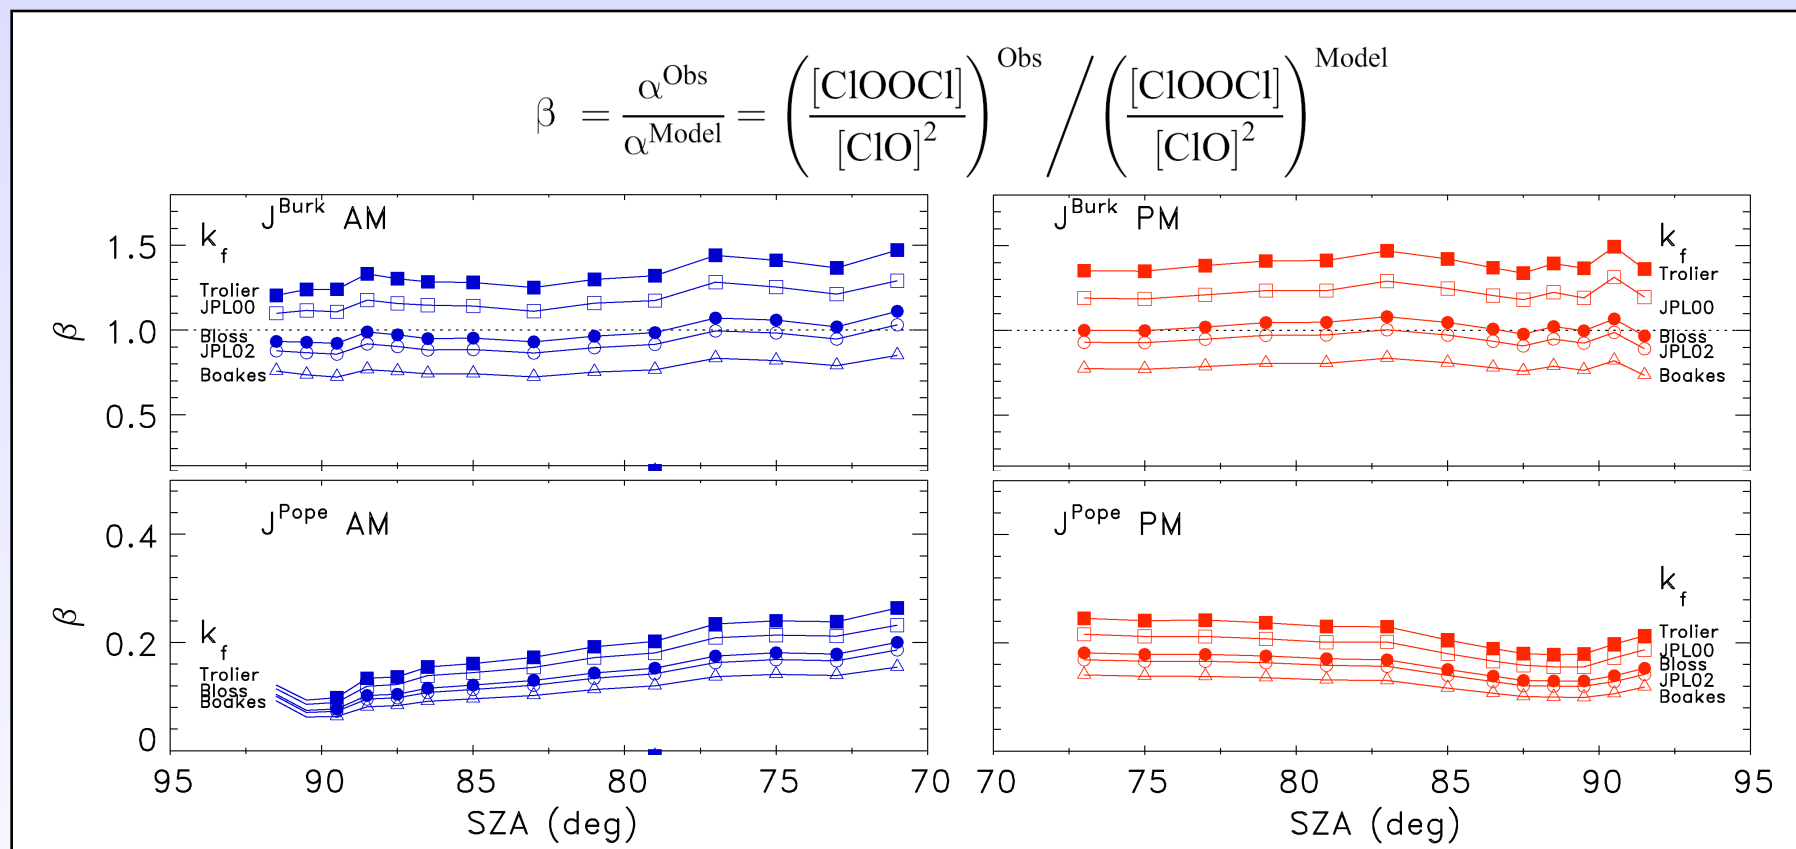

Frieler et al., GRL 2006; WMO 2006

# am/pm differences in efficient J ?

measurements during EUROSOLVE/SOLVE 2000  
analysis like in Stimpfle et al.(2004), but am/pm separately

=> ClO production rate similar to  $J_{\text{Burkholder}} \times [\text{Cl}_{\text{Havard}}]$  for all sza, for both am and pm)  
 $\text{Cl}_{\text{Havard}}$  = total Cl in all species that decompose at  $T \sim 370 \text{ K}$

=>  $J_{\text{Pope}}$  is not consistent with data and known chemistry

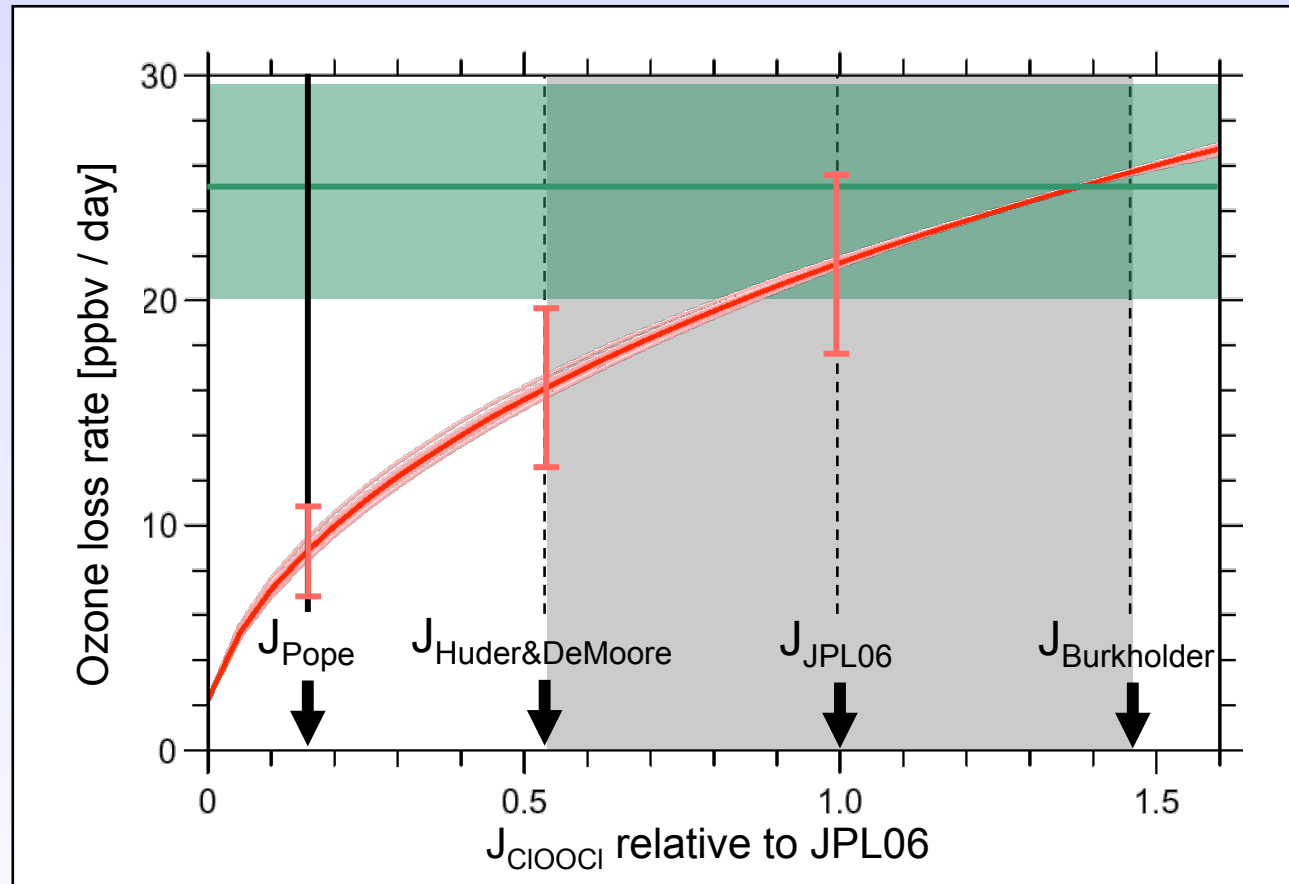

# Overall polar ozone loss rate versus $J_{\text{ClOOCl}}$

model constraint by measurements during SOLVE flight 000202  
ozone loss rates from Match

=> Best fit for  $J_{\text{Burkholder}}$ ,  $J_{\text{JPL06}}$  within uncertainties

=> no overlap of uncertainties for  $J < J_{\text{Huder\&DeMoore}}$

# ozone loss rate by ClO+ClO versus $J_{\text{ClOCl}}$

$\text{ClO}_x = 2 \text{ ppbv}$   
little sensitivity on  $k_{\text{eq}}$

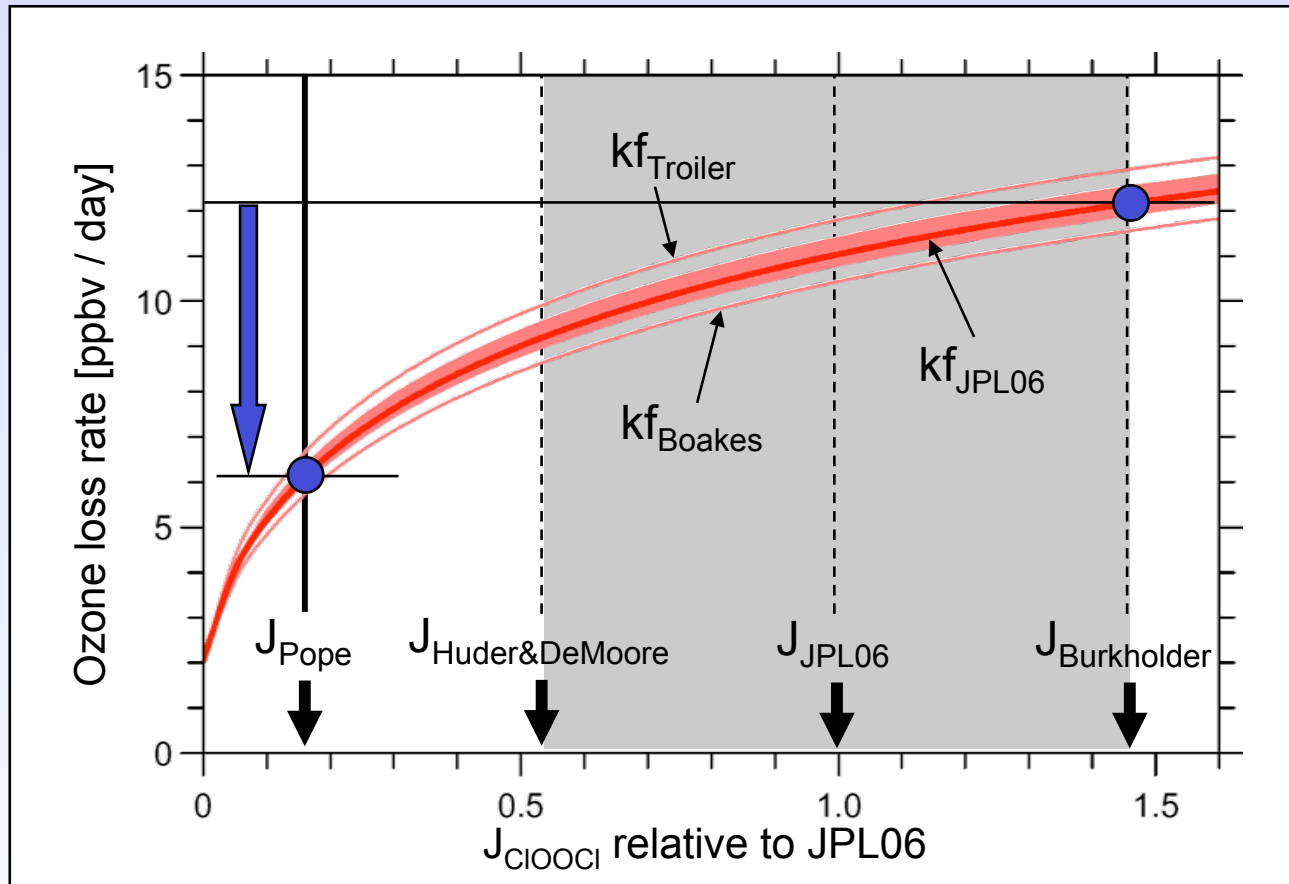

**=>  $J_{\text{Pope}}$  leads to reduction by more than 80%**

**=> ClO dimer cycle is no longer a major loss cycle**

# ozone loss rate by ClO+BrO versus $J_{\text{ClOOCl}}$

$\text{ClO}_x = 2 \text{ ppbv}$   
little sensitivity on  $k_{\text{eq}}$

**=>  $J_{\text{Pope}}$  leads to reduction by ~50%**

# ClO / (ClO + 2ClOOCl) versus $J_{\text{ClOOCl}}$

sza = 82.5°, pm, little sensitivity on keq

measurements during SOLVE 2000, flight 000202

=>  $J_{\text{Burkholder}}$  results in best fit to data (consistent with Stimpfle et al., 2004)

=>  $J_{\text{Pope}}$  is not consistent with in situ data => if correct: unknown chemistry
